WS 2017/18

# **Efficient Algorithms and Data Structures**

Harald Räcke

Fakultät für Informatik TU München

http://www14.in.tum.de/lehre/2017WS/ea/

Winter Term 2017/18

11. Apr. 2018 1/550

## Part I

## **Organizational Matters**

11. Apr. 2018 2/550

## Part I

## **Organizational Matters**

- Modul: IN2003
- Name: "Efficient Algorithms and Data Structures" "Effiziente Algorithmen und Datenstrukturen"
- ECTS: 8 Credit points
- Lectures:

 4 SWS Mon 10:00-12:00 (Room Interim2) Fri 10:00-12:00 (Room Interim2)

Webpage: http://www14.in.tum.de/lehre/2017WS/ea/

Required knowledge:

IN0001, IN0003

"Introduction to Informatics 1/2"

"Einführung in die Informatik 1/2"

IN0007

"Fundamentals of Algorithms and Data Structures"

"Grundlagen: Algorithmen und Datenstrukturen" (GAD)

IN0011

#### "Basic Theoretic Informatics"

"Einführung in die Theoretische Informatik" (THEO)

IN0015

#### "Discrete Structures"

"Diskrete Strukturen" (DS)

IN0018

#### "Discrete Probability Theory"

"Diskrete Wahrscheinlichkeitstheorie" (DWT)

## **The Lecturer**

- Harald Räcke
- Email: raecke@in.tum.de
- Room: 03.09.044
- Office hours: (by appointment)

## **Tutorials**

- A01 Monday, 12:00-14:00, 00.08.038 (Schmid)
- A02 Monday, 12:00-14:00, 00.09.038 (Stotz)
- A03 Monday, 14:00-16:00, 02.09.023 (Liebl)
- **B04** Tuesday, 10:00–12:00, 00.08.053 (Schmid) **B05** Tuesday, 12:00–14:00, 03.11.018 (Kraft)
- B06 Tuesday, 14:00-16:00, 00.08.038 (Somogyi)
- D07 Thursday, 10:00-12:00, 03.11.018 (Liebl)
- E08 Friday, 12:00-14:00, 00.13.009 (Stotz) E09 Friday, 14:00-16:00, 00.13.009 (Kraft)

## **Assignment sheets**

#### In order to pass the module you need to pass an exam.

11. Apr. 2018 7/550

Assignment Sheets:

- An assignment sheet is usually made available on Monday on the module webpage.
- Solutions have to be handed in in the following week before the lecture on Monday.
- You can hand in your solutions by putting them in the mailbox "Efficient Algorithms" on the basement floor in the MI-building.
- Solutions have to be given in English.
- Solutions will be discussed in the tutorial of the week when the sheet has been handed in, i.e, sheet may not be corrected by this time.
- > You can submit solutions in groups of up to 2 people.

Assignment Sheets:

- Submissions must be handwritten by a member of the group. Please indicate who wrote the submission.
- Don't forget name and student id number for each group member.

Assignment can be used to improve you grade

If you obtain a bonus your grade will improve according to the following function

$$f(x) = \begin{cases} \frac{1}{10} \operatorname{round}\left(10\left(\frac{\operatorname{round}(3x)-1}{3}\right)\right) & 1 < x \le 4\\ x & \text{otw.} \end{cases}$$

- It will improve by 0.3 or 0.4, respectively. Examples:
  - 3.3 → 3.0
  - 2.0 → 1.7
  - 3.7 → 3.3
  - 1.0 → 1.0
  - > 4.0 no improvement

#### **Requirements for Bonus**

- ▶ 50% of the points are achieved on submissions 2-8,
- 50% of the points are achieved on submissions 9-14,
- each group member has written at least 4 solutions.

## **1** Contents

#### Foundations

- Machine models
- Efficiency measures
- Asymptotic notation
- Recursion
- Higher Data Structures
  - Search trees
  - Hashing
  - Priority queues
  - Union/Find data structures
- Cuts/Flows
- Matchings

## Part II

## **Foundations**

11. Apr. 2018 16/550

## 3 Goals

- Gain knowledge about efficient algorithms for important problems, i.e., learn how to solve certain types of problems efficiently.
- Learn how to analyze and judge the efficiency of algorithms.
- Learn how to design efficient algorithms.

#### What do you measure?

- Memory requirement
- Running time
- Number of comparisons
- Number of multiplications
- Number of hard-disc accesses
- Program size
- Power consumption

#### How do you measure?

- Implementing and testing on representative inputs
  - How do you choose your inputs?
  - May be very time-consuming.
  - Very reliable results if done correctly.
  - Results only hold for a specific machine and for a specific set of inputs.
- Theoretical analysis in a specific model of computation.
  - Gives asymptotic bounds like "this algorithm always runs in time  $\mathcal{O}(n^2)$ ".
  - Typically focuses on the worst case.
  - Can give lower bounds like "any comparison-based sorting algorithm needs at least Ω(n log n) comparisons in the worst case".

#### Input length

The theoretical bounds are usually given by a function  $f : \mathbb{N} \to \mathbb{N}$  that maps the input length to the running time (or storage space, comparisons, multiplications, program size etc.).

The input length may e.g. be

- the size of the input (number of bits)
- the number of arguments

#### Example 1

Suppose *n* numbers from the interval  $\{1, ..., N\}$  have to be sorted. In this case we usually say that the input length is *n* instead of e.g.  $n \log N$ , which would be the number of bits required to encode the input.

4 Modelling Issues

## **Model of Computation**

#### How to measure performance

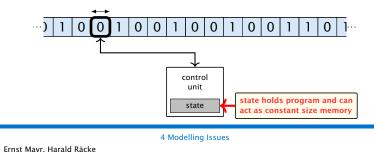

- Calculate running time and storage space etc. on a simplified, idealized model of computation, e.g. Random Access Machine (RAM), Turing Machine (TM), ...
- 2. Calculate number of certain basic operations: comparisons, multiplications, harddisc accesses, ...

Version 2. is often easier, but focusing on one type of operation makes it more difficult to obtain meaningful results.

## **Turing Machine**

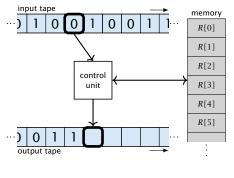

- Very simple model of computation.
- Only the "current" memory location can be altered.
- Very good model for discussing computabiliy, or polynomial vs. exponential time.
- Some simple problems like recognizing whether input is of the form xx, where x is a string, have quadratic lower bound.
- $\Rightarrow$  Not a good model for developing efficient algorithms.

11. Apr. 2018 22/550

## Random Access Machine (RAM)

- Input tape and output tape (sequences of zeros and ones; unbounded length).
- Memory unit: infinite but countable number of registers R[0], R[1], R[2], ....
- Registers hold integers.
- Indirect addressing.

Note that in the picture on the right the tapes are one-directional, and that a READ- or WRITE-operation always advances its tape.

Ernst Mavr. Harald Räcke

4 Modelling Issues

11. Apr. 2018 23/550

## Random Access Machine (RAM)

### Operations

• input operations (input tape  $\rightarrow R[i]$ )

▶ READ *i* 

• output operations ( $R[i] \rightarrow$  output tape)

▶ WRITE *i* 

- register-register transfers
  - $\blacktriangleright R[j] := R[i]$
  - $\blacktriangleright R[j] := 4$
- indirect addressing
  - $\blacktriangleright R[j] := R[R[i]]$

loads the content of the R[i]-th register into the j-th register

 $\blacktriangleright R[R[i]] := R[j]$ 

loads the content of the j-th into the R[i]-th register

## Random Access Machine (RAM)

#### Operations

branching (including loops) based on comparisons

jump x jumps to position x in the program; sets instruction counter to x; reads the next operation to perform from register R[x]
jumpz x R[i] jump to x if R[i] = 0 if not the instruction counter is increased by 1;
jumpi i jump to R[i] (indirect jump);
arithmetic instructions: +, -, ×, /

```
R[i] := R[j] + R[k];
R[i] := -R[k];
```

The jump-directives are very close to the jump-instructions contained in the assembler language of real machines.

## **Model of Computation**

- uniform cost model
   Every operation takes time 1.
- logarithmic cost model

The cost depends on the content of memory cells:

- The time for a step is equal to the largest operand involved;
- The storage space of a register is equal to the length (in bits) of the largest value ever stored in it.

**Bounded word RAM model:** cost is uniform but the largest value stored in a register may not exceed  $2^w$ , where usually  $w = \log_2 n$ .

The latter model is quite realistic as the word-size of a standard computer that handles a problem of size n must be at least  $\log_2 n$  as otherwise the computer could either not store the problem instance or not address all its memory.

#### Example 2

Algorithm 1 RepeatedSquaring(n)1:  $r \leftarrow 2$ ;2: for  $i = 1 \rightarrow n$  do3:  $r \leftarrow r^2$ 4: return r

- running time:
  - uniform model: n steps
  - logarithmic model:  $1 + 2 + 4 + \cdots + 2^n = 2^{n+1} 1 = \Theta(2^n)$
- space requirement:
  - uniform model:  $\mathcal{O}(1)$
  - logarithmic model:  $\mathcal{O}(2^n)$

There are different types of complexity bounds:

best-case complexity:

 $C_{\rm bc}(n) := \min\{C(x) \mid |x| = n\}$ 

Usually easy to analyze, but not very meaningful.

worst-case complexity:

```
C_{wc}(n) := \max\{C(x) \mid |x| = n\}
```

Usually moderately easy to analyze; sometimes too pessimistic.

```
average case complexity:
```

$$C_{\text{avg}}(n) := \frac{1}{|I_n|} \sum_{|x|=n} C(x)$$
  
more general: probability measure  $\mu$   
$$C_{\text{avg}}(n) := \sum_{x \in I_n} \mu(x) \cdot C(x)$$
$$\begin{bmatrix} C(x) & \text{cost of instance} \\ x & \text{input length of instance} \\ I_n & \text{set of instances} \\ \text{of length } n \end{bmatrix}$$

4 Modelling Issues

There are different types of complexity bounds:

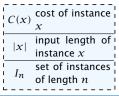

amortized complexity:

The average cost of data structure operations over a worst case sequence of operations.

randomized complexity:

The algorithm may use random bits. Expected running time (over all possible choices of random bits) for a fixed input

*x*. Then take the worst-case over all *x* with |x| = n.

Chapter 2.1 and 2.2 of [MS08] and Chapter 2 of [CLRS90] are relevant for this section.

4 Modelling Issues

11. Apr. 2018 29/550

We are usually not interested in exact running times, but only in an asymptotic classification of the running time, that ignores constant factors and constant additive offsets.

- We are usually interested in the running times for large values of n. Then constant additive terms do not play an important role.
- An exact analysis (e.g. *exactly* counting the number of operations in a RAM) may be hard, but wouldn't lead to more precise results as the computational model is already quite a distance from reality.
- A linear speed-up (i.e., by a constant factor) is always possible by e.g. implementing the algorithm on a faster machine.
- Running time should be expressed by simple functions.

#### **Formal Definition**

#### Let f denote functions from $\mathbb N$ to $\mathbb R^+.$

- ▶  $\mathcal{O}(f) = \{g \mid \exists c > 0 \ \exists n_0 \in \mathbb{N}_0 \ \forall n \ge n_0 : [g(n) \le c \cdot f(n)]\}$ (set of functions that asymptotically grow not faster than f)
- $\Omega(f) = \{g \mid \exists c > 0 \ \exists n_0 \in \mathbb{N}_0 \ \forall n \ge n_0 \colon [g(n) \ge c \cdot f(n)]\}$ (set of functions that asymptotically grow not slower than f)
- $\Theta(f) = \Omega(f) \cap \mathcal{O}(f)$ (functions that asymptotically have the same growth as f)
- ▶  $o(f) = \{g \mid \forall c > 0 \exists n_0 \in \mathbb{N}_0 \forall n \ge n_0 : [g(n) \le c \cdot f(n)]\}$ (set of functions that asymptotically grow slower than f)
- ►  $\omega(f) = \{g \mid \forall c > 0 \exists n_0 \in \mathbb{N}_0 \forall n \ge n_0 : [g(n) \ge c \cdot f(n)]\}$ (set of functions that asymptotically grow faster than f)

There is an equivalent definition using limes notation (assuming that the respective limes exists). f and g are functions from  $\mathbb{N}_0$  to  $\mathbb{R}_0^+$ .

• 
$$g \in \mathcal{O}(f)$$
:  $0 \le \lim_{n \to \infty} \frac{g(n)}{f(n)} < \infty$   
•  $g \in \Omega(f)$ :  $0 < \lim_{n \to \infty} \frac{g(n)}{f(n)} \le \infty$   
•  $g \in \Theta(f)$ :  $0 < \lim_{n \to \infty} \frac{g(n)}{f(n)} < \infty$   
•  $g \in o(f)$ :  $\lim_{n \to \infty} \frac{g(n)}{f(n)} = 0$   
•  $g \in \omega(f)$ :  $\lim_{n \to \infty} \frac{g(n)}{f(n)} = \infty$ 

- Note that for the version of the Landau notation defined here, we assume that *f* and *g* are positive functions.
- There also exist versions for arbitrary functions, and for the case that the limes is not infinity.

**5** Asymptotic Notation

#### Abuse of notation

- 1. People write f = O(g), when they mean  $f \in O(g)$ . This is **not** an equality (how could a function be equal to a set of functions).
- **2.** People write  $f(n) = \mathcal{O}(g(n))$ , when they mean  $f \in \mathcal{O}(g)$ , with  $f : \mathbb{N} \to \mathbb{R}^+, n \mapsto f(n)$ , and  $g : \mathbb{N} \to \mathbb{R}^+, n \mapsto g(n)$ .
- **3.** People write e.g. h(n) = f(n) + o(g(n)) when they mean that there exists a function  $z : \mathbb{N} \to \mathbb{R}^+, n \mapsto z(n), z \in o(g)$  such that h(n) = f(n) + z(n).

**2.** In this context f(n) does **not** mean the function f evaluated at n, but instead it is a shorthand for the function itself (leaving out domain and codomain and only giving the rule of correspondence of the function).

**3.** This is particularly useful if you do not want to ignore constant factors. For example the median of n elements can be determined using  $\frac{3}{2}n + o(n)$  comparisons.

#### Abuse of notation

**4.** People write  $\mathcal{O}(f(n)) = \mathcal{O}(g(n))$ , when they mean  $\mathcal{O}(f(n)) \subseteq \mathcal{O}(g(n))$ . Again this is not an equality.

2. In this context f(n) does **not** mean the function f evaluated at n, but instead it is a shorthand for the function itself (leaving out domain and codomain and only giving the rule of correspondence of the function).

**3.** This is particularly useful if you do not want to ignore constant factors. For example the median of n elements can be determined using  $\frac{3}{2}n + o(n)$  comparisons.

## **Asymptotic Notation in Equations**

How do we interpret an expression like:

$$2n^2 + 3n + 1 = 2n^2 + \Theta(n)$$

Here,  $\Theta(n)$  stands for an anonymous function in the set  $\Theta(n)$  that makes the expression true.

Note that  $\Theta(n)$  is on the right hand side, otw. this interpretation is wrong.

How do we interpret an expression like:

 $2n^2 + \mathcal{O}(n) = \Theta(n^2)$ 

Regardless of how we choose the anonymous function  $f(n) \in \mathcal{O}(n)$  there is an anonymous function  $g(n) \in \Theta(n^2)$  that makes the expression true.

5 Asymptotic Notation

How do we interpret an expression like:

```
\sum_{i=1}^n \Theta(i) = \Theta(n^2)
```

#### Careful!

"It is understood" that every occurence of an  $\mathcal{O}$ -symbol (or  $\Theta, \Omega, o, \omega$ ) on the left represents one anonymous function.

Hence, the left side is not equal to

 $\Theta(1) + \Theta(2) + \cdots + \Theta(n-1) + \Theta(n)$ 

The  $\Theta(i)$ -symbol on the left rep-

resents one anonymous function  $f: \mathbb{N} \to \mathbb{R}^+$ , and then  $\sum_i f(i)$  is

computed.

We can view an expression containing asymptotic notation as generating a set:

 $n^2 \cdot \mathcal{O}(n) + \mathcal{O}(\log n)$ 

represents

$$\begin{cases} f: \mathbb{N} \to \mathbb{R}^+ \mid f(n) = n^2 \cdot g(n) + h(n) \\ \text{with } g(n) \in \mathcal{O}(n) \text{ and } h(n) \in \mathcal{O}(\log n) \\ \text{Recall that according to the previous } \\ \text{slide e.g. the expressions } \sum_{i=1}^n \mathcal{O}(i) \text{ and } \\ \sum_{i=1}^{n/2} \mathcal{O}(i) + \sum_{i=n/2+1}^n \mathcal{O}(i) \text{ generate different sets.} \end{cases}$$

**5** Asymptotic Notation

Then an asymptotic equation can be interpreted as containement btw. two sets:

 $n^2 \cdot \mathcal{O}(n) + \mathcal{O}(\log n) = \Theta(n^2)$ 

represents

$$n^2 \cdot \mathcal{O}(n) + \mathcal{O}(\log n) \subseteq \Theta(n^2)$$

Note that the equation does not hold.

**5** Asymptotic Notation

11. Apr. 2018 37/550

#### Lemma 3

Let f, g be functions with the property

 $\exists n_0 > 0 \ \forall n \ge n_0$ : f(n) > 0 (the same for g). Then

- $c \cdot f(n) \in \Theta(f(n))$  for any constant c
- $\blacktriangleright \mathcal{O}(f(n)) + \mathcal{O}(g(n)) = \mathcal{O}(f(n) + g(n))$
- $\blacktriangleright \ \mathcal{O}(f(n)) \cdot \mathcal{O}(g(n)) = \mathcal{O}(f(n) \cdot g(n))$
- $\blacktriangleright \mathcal{O}(f(n)) + \mathcal{O}(g(n)) = \mathcal{O}(\max\{f(n), g(n)\})$

The expressions also hold for  $\Omega$ . Note that this means that  $f(n) + g(n) \in \Theta(\max\{f(n), g(n)\})$ .

#### Comments

- Do not use asymptotic notation within induction proofs.
- For any constants *a*, *b* we have log<sub>a</sub> n = Θ(log<sub>b</sub> n). Therefore, we will usually ignore the base of a logarithm within asymptotic notation.
- ▶ In general  $\log n = \log_2 n$ , i.e., we use 2 as the default base for the logarithm.

In general asymptotic classification of running times is a good measure for comparing algorithms:

- If the running time analysis is tight and actually occurs in practise (i.e., the asymptotic bound is not a purely theoretical worst-case bound), then the algorithm that has better asymptotic running time will always outperform a weaker algorithm for large enough values of n.
- However, suppose that I have two algorithms:
  - Algorithm A. Running time  $f(n) = 1000 \log n = O(\log n)$ .
  - Algorithm B. Running time  $g(n) = \log^2 n$ .

Clearly f = o(g). However, as long as  $\log n \le 1000$ Algorithm B will be more efficient.

#### Bibliography

- [MS08] Kurt Mehlhorn, Peter Sanders: Algorithms and Data Structures — The Basic Toolbox, Springer, 2008

Mainly Chapter 3 of [CLRS90]. [MS08] covers this topic in chapter 2.1 but not very detailed.

**5** Asymptotic Notation

11. Apr. 2018 41/550

#### **6 Recurrences**

Algorithm 2 mergesort(list L)1:  $n \leftarrow size(L)$ 2: if  $n \leq 1$  return L3:  $L_1 \leftarrow L[1 \cdots \lfloor \frac{n}{2}]]$ 4:  $L_2 \leftarrow L[\lfloor \frac{n}{2} \rfloor + 1 \cdots n]$ 5: mergesort(L\_1)6: mergesort(L\_2)7:  $L \leftarrow merge(L_1, L_2)$ 8: return L

This algorithm requires

 $T(n) = T\left(\left\lceil \frac{n}{2} \right\rceil\right) + T\left(\left\lfloor \frac{n}{2} \right\rfloor\right) + \mathcal{O}(n) \le 2T\left(\left\lceil \frac{n}{2} \right\rceil\right) + \mathcal{O}(n)$ 

comparisons when n > 1 and 0 comparisons when  $n \le 1$ .

6 Recurrences

# How do we bring the expression for the number of comparisons ( $\approx$ running time) into a closed form?

For this we need to solve the recurrence.

**6** Recurrences

11. Apr. 2018 42/550

## **Methods for Solving Recurrences**

#### 1. Guessing+Induction

Guess the right solution and prove that it is correct via induction. It needs experience to make the right guess.

#### 2. Master Theorem

For a lot of recurrences that appear in the analysis of algorithms this theorem can be used to obtain tight asymptotic bounds. It does not provide exact solutions.

#### 3. Characteristic Polynomial

Linear homogenous recurrences can be solved via this method.

6 Recurrences

### **Methods for Solving Recurrences**

#### 4. Generating Functions

A more general technique that allows to solve certain types of linear inhomogenous relations and also sometimes non-linear recurrence relations.

#### 5. Transformation of the Recurrence

Sometimes one can transform the given recurrence relations so that it e.g. becomes linear and can therefore be solved with one of the other techniques.

6 Recurrences

First we need to get rid of the  $\mathcal{O}$ -notation in our recurrence:

$$T(n) \leq \begin{cases} 2T(\left\lceil \frac{n}{2} \right\rceil) + cn & n \ge 2\\ 0 & \text{otherwise} \end{cases}$$

#### Informal way:

Assume that instead we have

$$T(n) \leq \begin{cases} 2T(\frac{n}{2}) + cn & n \ge 2\\ 0 & \text{otherwise} \end{cases}$$

One way of solving such a recurrence is to guess a solution, and check that it is correct by plugging it in.

Suppose we guess  $T(n) \le dn \log n$  for a constant *d*. Then

$$T(n) \le 2T\left(\frac{n}{2}\right) + cn$$
  
$$\le 2\left(d\frac{n}{2}\log\frac{n}{2}\right) + cn$$
  
$$= dn(\log n - 1) + cn$$
  
$$= dn\log n + (c - d)n$$
  
$$\le dn\log n$$

if we choose  $d \ge c$ .

Formally, this is not correct if n is not a power of 2. Also even in this case one would need to do an induction proof.

How do we get a result for all values of n?

We consider the following recurrence instead of the original one:

$$T(n) \le \begin{cases} 2T(\left\lceil \frac{n}{2} \right\rceil) + cn & n \ge 16\\ b & \text{otherwise} \end{cases}$$

Note that we can do this as for constant-sized inputs the running time is always some constant (*b* in the above case).

We also make a guess of  $T(n) \leq dn \log n$  and get

$$T(n) \leq 2T\left(\left\lceil \frac{n}{2} \right\rceil\right) + cn$$

$$\leq 2\left(d\left\lceil \frac{n}{2} \right\rceil \log\left\lceil \frac{n}{2} \right\rceil\right) + cn$$

$$\left\lceil \frac{n}{2} \right\rceil \leq \frac{n}{2} + 1 \leq 2\left(d(n/2+1)\log(n/2+1)\right) + cn$$

$$\frac{n}{2} + 1 \leq \frac{9}{16}n \leq dn \log\left(\frac{9}{16}n\right) + 2d \log n + cn$$

$$\log \frac{9}{16}n = \log n + (\log 9 - 4) = dn \log n + (\log 9 - 4)dn + 2d \log n + cn$$

$$\log n \leq \frac{n}{4} \leq dn \log n + (\log 9 - 3.5)dn + cn$$

$$\leq dn \log n - 0.33dn + cn$$

$$\leq dn \log n$$

for a suitable choice of d.

### 6.2 Master Theorem

Note that the cases do not cover all possibilities.

#### Lemma 4

Let  $a \ge 1, b \ge 1$  and  $\epsilon > 0$  denote constants. Consider the recurrence

$$T(n) = aT\left(\frac{n}{b}\right) + f(n) \; .$$

Case 1. If  $f(n) = O(n^{\log_b(a)-\epsilon})$  then  $T(n) = O(n^{\log_b a})$ .

Case 2. If  $f(n) = \Theta(n^{\log_b(a)} \log^k n)$  then  $T(n) = \Theta(n^{\log_b a} \log^{k+1} n)$ ,  $k \ge 0$ .

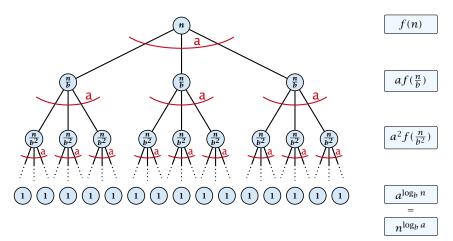

*Case 3.* If  $f(n) = \Omega(n^{\log_b(a)+\epsilon})$  and for sufficiently large n $af(\frac{n}{b}) \le cf(n)$  for some constant c < 1 then  $T(n) = \Theta(f(n))$ . We prove the Master Theorem for the case that n is of the form  $b^{\ell}$ , and we assume that the non-recursive case occurs for problem size 1 and incurs cost 1.

6.2 Master Theorem

#### **The Recursion Tree**

The running time of a recursive algorithm can be visualized by a recursion tree:

6.2 Master Theorem

11. Apr. 2018 51/550

#### 6.2 Master Theorem

This gives

$$T(n) = n^{\log_b a} + \sum_{i=0}^{\log_b n-1} a^i f\left(\frac{n}{b^i}\right) \ .$$

6.2 Master Theorem

11. Apr. 2018 52/550 Case 1. Now suppose that  $f(n) \leq c n^{\log_b a - \epsilon}$ .

$$T(n) - n^{\log_{b} a} = \sum_{i=0}^{\log_{b} n-1} a^{i} f\left(\frac{n}{b^{i}}\right)$$

$$\leq c \sum_{i=0}^{\log_{b} n-1} a^{i} \left(\frac{n}{b^{i}}\right)^{\log_{b} a-\epsilon}$$

$$\overline{b^{-i(\log_{b} a-\epsilon)} = b^{\epsilon i} (b^{\log_{b} a})^{-i} = b^{\epsilon i} a^{-i}} = c n^{\log_{b} a-\epsilon} \sum_{i=0}^{\log_{b} n-1} (b^{\epsilon})^{i}$$

$$\overline{\sum_{i=0}^{k} q^{i} = \frac{q^{k+1}-1}{q-1}} = c n^{\log_{b} a-\epsilon} (b^{\epsilon} \log_{b} n - 1)/(b^{\epsilon} - 1)$$

$$= c n^{\log_{b} a-\epsilon} (n^{\epsilon} - 1)/(b^{\epsilon} - 1)$$

$$= \frac{c}{b^{\epsilon} - 1} n^{\log_{b} a} (n^{\epsilon} - 1)/(n^{\epsilon})$$

Hence,

$$T(n) \leq \left(\frac{c}{b^{\epsilon}-1}+1\right) n^{\log_b(a)} \qquad \qquad \Rightarrow T(n) = \mathcal{O}(n^{\log_b a}).$$

6.2 Master Theorem

11. Apr. 2018 53/550 Case 2. Now suppose that  $f(n) \leq c n^{\log_b a}$ .

$$T(n) - n^{\log_b a} = \sum_{i=0}^{\log_b n-1} a^i f\left(\frac{n}{b^i}\right)$$
$$\leq c \sum_{i=0}^{\log_b n-1} a^i \left(\frac{n}{b^i}\right)^{\log_b a}$$
$$= c n^{\log_b a} \sum_{i=0}^{\log_b n-1} 1$$
$$= c n^{\log_b a} \log_b n$$

Hence,

 $T(n) = \mathcal{O}(n^{\log_b a} \log_b n) \qquad \Rightarrow T$ 

$$\Rightarrow T(n) = \mathcal{O}(n^{\log_b a} \log n).$$

6.2 Master Theorem

11. Apr. 2018 54/550 Case 2. Now suppose that  $f(n) \ge c n^{\log_b a}$ .

$$T(n) - n^{\log_b a} = \sum_{i=0}^{\log_b n-1} a^i f\left(\frac{n}{b^i}\right)$$
$$\ge c \sum_{i=0}^{\log_b n-1} a^i \left(\frac{n}{b^i}\right)^{\log_b a}$$
$$= c n^{\log_b a} \sum_{i=0}^{\log_b n-1} 1$$
$$= c n^{\log_b a} \log_b n$$

Hence,

 $T(n) = \mathbf{\Omega}(n^{\log_b a} \log_b n)$ 

$$\Rightarrow T(n) = \mathbf{\Omega}(n^{\log_b a} \log n).$$

6.2 Master Theorem

11. Apr. 2018 55/550 Case 2. Now suppose that  $f(n) \leq c n^{\log_b a} (\log_b(n))^k$ .

$$T(n) - n^{\log_{b} a} = \sum_{i=0}^{\log_{b} n-1} a^{i} f\left(\frac{n}{b^{i}}\right)$$

$$\leq c \sum_{i=0}^{\log_{b} n-1} a^{i} \left(\frac{n}{b^{i}}\right)^{\log_{b} a} \cdot \left(\log_{b} \left(\frac{n}{b^{i}}\right)\right)^{k}$$

$$\overline{n = b^{\ell} \Rightarrow \ell = \log_{b} n} = c n^{\log_{b} a} \sum_{i=0}^{\ell-1} \left(\log_{b} \left(\frac{b^{\ell}}{b^{i}}\right)\right)^{k}$$

$$= c n^{\log_{b} a} \sum_{i=0}^{\ell-1} (\ell - i)^{k}$$

$$= c n^{\log_{b} a} \sum_{i=1}^{\ell} i^{k} \approx \frac{1}{k} \ell^{k+1}$$

$$\approx \frac{c}{k} n^{\log_{b} a} \ell^{k+1} \qquad \Rightarrow T(n) = \mathcal{O}(n^{\log_{b} a} \log^{k+1} n)^{k}$$

Case 3. Now suppose that  $f(n) \ge dn^{\log_b a+\epsilon}$ , and that for sufficiently large n:  $af(n/b) \le cf(n)$ , for c < 1.

From this we get  $a^i f(n/b^i) \le c^i f(n)$ , where we assume that  $n/b^{i-1} \ge n_0$  is still sufficiently large.

$$T(n) - n^{\log_{b} a} = \sum_{i=0}^{\log_{b} n-1} a^{i} f\left(\frac{n}{b^{i}}\right)$$
$$\leq \sum_{i=0}^{\log_{b} n-1} c^{i} f(n) + \mathcal{O}(n^{\log_{b} a})$$
$$\leq 1: \sum_{i=0}^{n} q^{i} = \frac{1-q^{n+1}}{1-q} \leq \frac{1}{1-q} \leq \frac{1}{1-c} f(n) + \mathcal{O}(n^{\log_{b} a})$$

Hence,

q <

$$T(n) \leq \mathcal{O}(f(n))$$

$$\Rightarrow T(n) = \Theta(f(n)).$$

Where did we use  $f(n) \ge \Omega(n^{\log_b a + \epsilon})$ ?

Ernst Mayr, Harald Räcke

6.2 Master Theorem

11. Apr. 2018 57/550

Suppose we want to multiply two n-bit Integers, but our registers can only perform operations on integers of constant size.

For this we first need to be able to add two integers **A** and **B**:

#### 

This gives that two *n*-bit integers can be added in time O(n).

Suppose that we want to multiply an *n*-bit integer A and an *m*-bit integer B ( $m \le n$ ).

	1	0	0	0	1	Х	1	0	1	1
			_			1	0	0	0	1
• This is also nown as the "school method" for multiplying integers.					1	0	0	0	1	0
• Note that the intermedia bers that are generated				0	_	0			-	-
at most $m + n \le 2n$ bits			<u>_1</u>	0	0	0	1	0	0	0
-			1	0	1	1	1	0	1	1

#### Time requirement:

- Computing intermediate results: O(nm).
- Adding *m* numbers of length  $\leq 2n$ :

 $\mathcal{O}((m+n)m) = \mathcal{O}(nm).$ 

#### A recursive approach:

Suppose that integers **A** and **B** are of length  $n = 2^k$ , for some k.

$$\begin{array}{|c|c|c|c|c|c|} B_1 & B_0 & \times & A_1 & A_0 \\ \hline \end{array}$$

Then it holds that

$$A = A_1 \cdot 2^{\frac{n}{2}} + A_0$$
 and  $B = B_1 \cdot 2^{\frac{n}{2}} + B_0$ 

Hence,

$$A \cdot B = A_1 B_1 \cdot 2^n + (A_1 B_0 + A_0 B_1) \cdot 2^{\frac{n}{2}} + A_0 B_0$$

6.2 Master Theorem

11. Apr. 2018 60/550

Algorithm 3 mult(A, B)	
1: if $ A  =  B  = 1$ then	$\mathcal{O}(1)$
2: <b>return</b> $a_0 \cdot b_0$	$\mathcal{O}(1)$
3: split $A$ into $A_0$ and $A_1$	$\mathcal{O}(n)$
4: split <i>B</i> into $B_0$ and $B_1$	$\mathcal{O}(n)$
5: $Z_2 \leftarrow \operatorname{mult}(A_1, B_1)$	$T(\frac{n}{2})$
6: $Z_1 \leftarrow \operatorname{mult}(A_1, B_0) + \operatorname{mult}(A_0, B_1)$	$2T(\frac{n}{2}) + \mathcal{O}(n)$
7: $Z_0 \leftarrow \operatorname{mult}(A_0, B_0)$	$T(\frac{n}{2})$
8: <b>return</b> $Z_2 \cdot 2^n + Z_1 \cdot 2^{\frac{n}{2}} + Z_0$	$\mathcal{O}(n)$

We get the following recurrence:

$$T(n) = 4T\left(\frac{n}{2}\right) + \mathcal{O}(n)$$
.

6.2 Master Theorem

11. Apr. 2018 61/550

**Master Theorem:** Recurrence:  $T[n] = aT(\frac{n}{b}) + f(n)$ .

• Case 1: 
$$f(n) = O(n^{\log_b a - \epsilon})$$
  $T(n) = O(n^{\log_b a})$ 

• Case 2: 
$$f(n) = \Theta(n^{\log_b a} \log^k n)$$
  $T(n) = \Theta(n^{\log_b a} \log^{k+1} n)$ 

• Case 3:  $f(n) = \Omega(n^{\log_b a + \epsilon})$   $T(n) = \Theta(f(n))$ 

In our case a = 4, b = 2, and  $f(n) = \Theta(n)$ . Hence, we are in Case 1, since  $n = O(n^{2-\epsilon}) = O(n^{\log_b a - \epsilon})$ .

We get a running time of  $\mathcal{O}(n^2)$  for our algorithm.

 $\Rightarrow$  Not better then the "school method".

We can use the following identity to compute  $Z_1$ :

$$Z_1 = A_1 B_0 + A_0 B_1 = Z_2 = Z_0$$
  
= (A\_0 + A\_1) \cdots (B\_0 + B\_1) - A\_1 B\_1 - A\_0 B\_0

Hence,		
fichec,	Algorithm 4 mult(A, B)	
	1: if $ A  =  B  = 1$ then	$\mathcal{O}(1)$
	2: <b>return</b> $a_0 \cdot b_0$	$\mathcal{O}(1)$
	3: split $A$ into $A_0$ and $A_1$	$\mathcal{O}(n)$
	4: split <i>B</i> into $B_0$ and $B_1$	$\mathcal{O}(n)$
A more precise	5: $Z_2 \leftarrow \operatorname{mult}(A_1, B_1)$	$T(\frac{n}{2})$
(correct) analysis	6: $Z_0 \leftarrow \operatorname{mult}(A_0, B_0)$	$T(\frac{n}{2})$
would say that computing $Z_1$	7: $Z_1 \leftarrow \text{mult}(A_0 + A_1, B_0 + B_1) - Z_2 - Z_0$	$T(\frac{n}{2}) + \mathcal{O}(n)$
needs time	8: return $Z_2 \cdot 2^n + Z_1 \cdot 2^{\frac{n}{2}} + Z_0$	$\mathcal{O}(n)$
$T(\frac{n}{2}+1)+\mathcal{O}(n).$		

6.2 Master Theorem

Ernst Mayr, Harald Räcke

We get the following recurrence:

$$T(n) = 3T\left(\frac{n}{2}\right) + \mathcal{O}(n) \ .$$

**Master Theorem:** Recurrence:  $T[n] = aT(\frac{n}{b}) + f(n)$ .

- Case 1:  $f(n) = O(n^{\log_b a \epsilon})$   $T(n) = \Theta(n^{\log_b a})$
- Case 2:  $f(n) = \Theta(n^{\log_b a} \log^k n)$   $T(n) = \Theta(n^{\log_b a} \log^{k+1} n)$
- Case 3:  $f(n) = \Omega(n^{\log_b a + \epsilon})$   $T(n) = \Theta(f(n))$

Again we are in Case 1. We get a running time of  $\Theta(n^{\log_2 3}) \approx \Theta(n^{1.59})$ .

#### A huge improvement over the "school method".

### 6.3 The Characteristic Polynomial

Consider the recurrence relation:

 $c_0T(n) + c_1T(n-1) + c_2T(n-2) + \cdots + c_kT(n-k) = f(n)$ 

This is the general form of a linear recurrence relation of order k with constant coefficients ( $c_0, c_k \neq 0$ ).

- T(n) only depends on the k preceding values. This means the recurrence relation is of order k.
- The recurrence is linear as there are no products of T[n]'s.
- If f(n) = 0 then the recurrence relation becomes a linear, homogenous recurrence relation of order k.

Note that we ignore boundary conditions for the moment.

## 6.3 The Characteristic Polynomial

#### **Observations:**

- The solution T[1], T[2], T[3],... is completely determined by a set of boundary conditions that specify values for T[1],...,T[k].
- In fact, any k consecutive values completely determine the solution.
- k non-concecutive values might not be an appropriate set of boundary conditions (depends on the problem).

#### Approach:

- First determine all solutions that satisfy recurrence relation.
- Then pick the right one by analyzing boundary conditions.
- First consider the homogenous case.

#### **The Homogenous Case**

The solution space

 $S = \left\{ \mathcal{T} = T[1], T[2], T[3], \dots \mid \mathcal{T} \text{ fulfills recurrence relation} \right\}$ 

is a vector space. This means that if  $\mathcal{T}_1, \mathcal{T}_2 \in S$ , then also  $\alpha \mathcal{T}_1 + \beta \mathcal{T}_2 \in S$ , for arbitrary constants  $\alpha, \beta$ .

#### How do we find a non-trivial solution?

We guess that the solution is of the form  $\lambda^n$ ,  $\lambda \neq 0$ , and see what happens. In order for this guess to fulfill the recurrence we need

$$c_0\lambda^n + c_1\lambda^{n-1} + c_2 \cdot \lambda^{n-2} + \dots + c_k \cdot \lambda^{n-k} = 0$$

for all  $n \ge k$ .

#### The Homogenous Case

Dividing by  $\lambda^{n-k}$  gives that all these constraints are identical to

$$\underbrace{c_0 \lambda^k + c_1 \lambda^{k-1} + c_2 \cdot \lambda^{k-2} + \dots + c_k}_{\text{characteristic polynomial } P[\lambda]} = 0$$

This means that if  $\lambda_i$  is a root (Nullstelle) of  $P[\lambda]$  then  $T[n] = \lambda_i^n$  is a solution to the recurrence relation.

Let  $\lambda_1, ..., \lambda_k$  be the k (complex) roots of  $P[\lambda]$ . Then, because of the vector space property

$$\alpha_1\lambda_1^n + \alpha_2\lambda_2^n + \cdots + \alpha_k\lambda_k^n$$

is a solution for arbitrary values  $\alpha_i$ .

# **The Homogenous Case**

Lemma 5

Assume that the characteristic polynomial has k distinct roots  $\lambda_1, \ldots, \lambda_k$ . Then all solutions to the recurrence relation are of the form

$$\alpha_1\lambda_1^n + \alpha_2\lambda_2^n + \cdots + \alpha_k\lambda_k^n$$
.

#### Proof.

There is one solution for every possible choice of boundary conditions for  $T[1], \ldots, T[k]$ .

We show that the above set of solutions contains one solution for every choice of boundary conditions.

### The Homogenous Case

#### Proof (cont.).

Suppose I am given boundary conditions T[i] and I want to see whether I can choose the  $\alpha'_i s$  such that these conditions are met:

$$\begin{aligned} \alpha_1 \cdot \lambda_1 &+ \alpha_2 \cdot \lambda_2 &+ \cdots &+ \alpha_k \cdot \lambda_k &= T[1] \\ \alpha_1 \cdot \lambda_1^2 &+ \alpha_2 \cdot \lambda_2^2 &+ \cdots &+ \alpha_k \cdot \lambda_k^2 &= T[2] \\ & & \vdots \\ \alpha_1 \cdot \lambda_1^k &+ \alpha_2 \cdot \lambda_2^k &+ \cdots &+ \alpha_k \cdot \lambda_k^k &= T[k] \end{aligned}$$

6.3 The Characteristic Polynomial

11. Apr. 2018 70/550

# **The Homogenous Case**

#### Proof (cont.).

Suppose I am given boundary conditions T[i] and I want to see whether I can choose the  $\alpha'_i s$  such that these conditions are met:

$$\begin{pmatrix} \lambda_1 & \lambda_2 & \cdots & \lambda_k \\ \lambda_1^2 & \lambda_2^2 & \cdots & \lambda_k^2 \\ & \vdots & & \\ \lambda_1^k & \lambda_2^k & \cdots & \lambda_k^k \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_k \end{pmatrix} = \begin{pmatrix} T[1] \\ T[2] \\ \vdots \\ T[k] \end{pmatrix}$$

We show that the column vectors are linearly independent. Then the above equation has a solution.

$$\begin{vmatrix} \lambda_{1} & \lambda_{2} & \cdots & \lambda_{k-1} & \lambda_{k} \\ \lambda_{1}^{2} & \lambda_{2}^{2} & \cdots & \lambda_{k-1}^{2} & \lambda_{k}^{2} \\ \vdots & \vdots & & \vdots & \vdots \\ \lambda_{1}^{k} & \lambda_{2}^{k} & \cdots & \lambda_{k-1}^{k} & \lambda_{k}^{k} \end{vmatrix} = \prod_{i=1}^{k} \lambda_{i} \cdot \begin{vmatrix} 1 & 1 & \cdots & 1 & 1 \\ \lambda_{1} & \lambda_{2} & \cdots & \lambda_{k-1} & \lambda_{k} \\ \vdots & \vdots & & \vdots & \vdots \\ \lambda_{1}^{k-1} & \lambda_{2}^{k-1} & \cdots & \lambda_{k-1}^{k-1} & \lambda_{k}^{k-1} \end{vmatrix}$$
$$= \prod_{i=1}^{k} \lambda_{i} \cdot \begin{vmatrix} 1 & \lambda_{1} & \cdots & \lambda_{1}^{k-2} & \lambda_{i-1}^{k-1} \\ \lambda_{1}^{k-1} & \lambda_{2}^{k-1} & \cdots & \lambda_{k-1}^{k-2} & \lambda_{k}^{k-1} \\ 1 & \lambda_{2} & \cdots & \lambda_{k-2}^{k-2} & \lambda_{k}^{k-1} \\ \vdots & \vdots & & \vdots & \vdots \\ 1 & \lambda_{k} & \cdots & \lambda_{k}^{k-2} & \lambda_{k}^{k-1} \end{vmatrix}$$

Ernst Mayr, Harald Räcke

6.3 The Characteristic Polynomial

11. Apr. 2018 72/550

$$\begin{vmatrix} \lambda_{1} & \cdots & \lambda_{1}^{k-2} & \lambda_{1}^{k-1} \\ 1 & \lambda_{2} & \cdots & \lambda_{2}^{k-2} & \lambda_{2}^{k-1} \\ \vdots & \vdots & \vdots & \vdots \\ 1 & \lambda_{k} & \cdots & \lambda_{k}^{k-2} & \lambda_{k}^{k-1} \end{vmatrix} = \\ \begin{vmatrix} 1 & \lambda_{1} - \lambda_{1} \cdot 1 & \cdots & \lambda_{1}^{k-2} - \lambda_{1} \cdot \lambda_{1}^{k-3} & \lambda_{1}^{k-1} - \lambda_{1} \cdot \lambda_{1}^{k-2} \\ 1 & \lambda_{2} - \lambda_{1} \cdot 1 & \cdots & \lambda_{2}^{k-2} - \lambda_{1} \cdot \lambda_{2}^{k-3} & \lambda_{2}^{k-1} - \lambda_{1} \cdot \lambda_{2}^{k-2} \\ \vdots & \vdots & \vdots & \vdots \\ 1 & \lambda_{k} - \lambda_{1} \cdot 1 & \cdots & \lambda_{k}^{k-2} - \lambda_{1} \cdot \lambda_{k}^{k-3} & \lambda_{k}^{k-1} - \lambda_{1} \cdot \lambda_{k}^{k-2} \end{vmatrix}$$

Ernst Mayr, Harald Räcke

6.3 The Characteristic Polynomial

11. Apr. 2018 73/550

Ernst Mayr, Harald Räcke

$$\begin{vmatrix} \lambda_1 - \lambda_1 \cdot 1 & \cdots & \lambda_1^{k-2} - \lambda_1 \cdot \lambda_1^{k-3} & \lambda_1^{k-1} - \lambda_1 \cdot \lambda_1^{k-2} \\ 1 & \lambda_2 - \lambda_1 \cdot 1 & \cdots & \lambda_2^{k-2} - \lambda_1 \cdot \lambda_2^{k-3} & \lambda_2^{k-1} - \lambda_1 \cdot \lambda_2^{k-2} \\ \vdots & \vdots & & \vdots & & \vdots \\ 1 & \lambda_k - \lambda_1 \cdot 1 & \cdots & \lambda_k^{k-2} - \lambda_1 \cdot \lambda_k^{k-3} & \lambda_k^{k-1} - \lambda_1 \cdot \lambda_k^{k-2} \end{vmatrix} = \\ \begin{vmatrix} 1 & 0 & \cdots & 0 & 0 \\ 1 & (\lambda_2 - \lambda_1) \cdot 1 & \cdots & (\lambda_2 - \lambda_1) \cdot \lambda_2^{k-3} & (\lambda_2 - \lambda_1) \cdot \lambda_2^{k-2} \\ \vdots & \vdots & & \vdots & & \vdots \\ 1 & (\lambda_k - \lambda_1) \cdot 1 & \cdots & (\lambda_k - \lambda_1) \cdot \lambda_k^{k-3} & (\lambda_k - \lambda_1) \cdot \lambda_k^{k-2} \end{vmatrix} =$$

6.3 The Characteristic Polynomial

11. Apr. 2018 74/550

$$\begin{vmatrix} 1 & 0 & \cdots & 0 & 0 \\ 1 & (\lambda_2 - \lambda_1) \cdot 1 & \cdots & (\lambda_2 - \lambda_1) \cdot \lambda_2^{k-3} & (\lambda_2 - \lambda_1) \cdot \lambda_2^{k-2} \\ \vdots & \vdots & \vdots & \vdots \\ 1 & (\lambda_k - \lambda_1) \cdot 1 & \cdots & (\lambda_k - \lambda_1) \cdot \lambda_k^{k-3} & (\lambda_k - \lambda_1) \cdot \lambda_k^{k-2} \end{vmatrix} = \\ \begin{bmatrix} k \\ \prod_{i=2}^k (\lambda_i - \lambda_1) \cdot \\ \vdots & \vdots & \vdots \\ 1 & \lambda_k & \cdots & \lambda_k^{k-3} & \lambda_k^{k-2} \\ \end{bmatrix}$$

6.3 The Characteristic Polynomial

11. Apr. 2018 75/550

Repeating the above steps gives:

$$\begin{vmatrix} \lambda_1 & \lambda_2 & \cdots & \lambda_{k-1} & \lambda_k \\ \lambda_1^2 & \lambda_2^2 & \cdots & \lambda_{k-1}^2 & \lambda_k^2 \\ \vdots & \vdots & & \vdots & \vdots \\ \lambda_1^k & \lambda_2^k & \cdots & \lambda_{k-1}^k & \lambda_k^k \end{vmatrix} = \prod_{i=1}^k \lambda_i \cdot \prod_{i>\ell} (\lambda_i - \lambda_\ell)$$

Hence, if all  $\lambda_i$ 's are different, then the determinant is non-zero.

6.3 The Characteristic Polynomial

11. Apr. 2018 76/550

#### What happens if the roots are not all distinct?

Suppose we have a root  $\lambda_i$  with multiplicity (Vielfachheit) at least 2. Then not only is  $\lambda_i^n$  a solution to the recurrence but also  $n\lambda_i^n$ .

To see this consider the polynomial

 $P[\lambda] \cdot \lambda^{n-k} = c_0 \lambda^n + c_1 \lambda^{n-1} + c_2 \lambda^{n-2} + \dots + c_k \lambda^{n-k}$ 

Since  $\lambda_i$  is a root we can write this as  $Q[\lambda] \cdot (\lambda - \lambda_i)^2$ . Calculating the derivative gives a polynomial that still has root  $\lambda_i$ .

#### This means

$$c_0 n \lambda_i^{n-1} + c_1 (n-1) \lambda_i^{n-2} + \dots + c_k (n-k) \lambda_i^{n-k-1} = 0$$

#### Hence,

$$c_0 \underbrace{n\lambda_i^n}_{T[n]} + c_1 \underbrace{(n-1)\lambda_i^{n-1}}_{T[n-1]} + \cdots + c_k \underbrace{(n-k)\lambda_i^{n-k}}_{T[n-k]} = 0$$

6.3 The Characteristic Polynomial

11. Apr. 2018 78/550

Suppose  $\lambda_i$  has multiplicity *j*. We know that

$$c_0 n \lambda_i^n + c_1 (n-1) \lambda_i^{n-1} + \dots + c_k (n-k) \lambda_i^{n-k} = 0$$

(after taking the derivative; multiplying with  $\lambda$ ; plugging in  $\lambda_i$ )

Doing this again gives

$$c_0 n^2 \lambda_i^n + c_1 (n-1)^2 \lambda_i^{n-1} + \dots + c_k (n-k)^2 \lambda_i^{n-k} = 0$$

We can continue j - 1 times.

Hence,  $n^{\ell}\lambda_i^n$  is a solution for  $\ell \in 0, ..., j-1$ .

Lemma 6

Let  $P[\lambda]$  denote the characteristic polynomial to the recurrence

 $c_0T[n] + c_1T[n-1] + \cdots + c_kT[n-k] = 0$ 

Let  $\lambda_i$ , i = 1, ..., m be the (complex) roots of  $P[\lambda]$  with multiplicities  $\ell_i$ . Then the general solution to the recurrence is given by

$$T[n] = \sum_{i=1}^{m} \sum_{j=0}^{\ell_i-1} \alpha_{ij} \cdot (n^j \lambda_i^n) .$$

The full proof is omitted. We have only shown that any choice of  $\alpha_{ij}$ 's is a solution to the recurrence.

# **Example: Fibonacci Sequence**

$$T[0] = 0$$
  
 $T[1] = 1$   
 $T[n] = T[n-1] + T[n-2]$  for  $n \ge 2$ 

The characteristic polynomial is

 $\lambda^2-\lambda-1$ 

Finding the roots, gives

$$\lambda_{1/2} = \frac{1}{2} \pm \sqrt{\frac{1}{4} + 1} = \frac{1}{2} \left( 1 \pm \sqrt{5} \right)$$

6.3 The Characteristic Polynomial

11. Apr. 2018 81/550

# **Example: Fibonacci Sequence**

Hence, the solution is of the form

$$\alpha \left(\frac{1+\sqrt{5}}{2}\right)^n + \beta \left(\frac{1-\sqrt{5}}{2}\right)^n$$

T[0] = 0 gives  $\alpha + \beta = 0$ .

T[1] = 1 gives

$$\alpha\left(\frac{1+\sqrt{5}}{2}\right)+\beta\left(\frac{1-\sqrt{5}}{2}\right)=1 \Longrightarrow \alpha-\beta=\frac{2}{\sqrt{5}}$$

6.3 The Characteristic Polynomial

11. Apr. 2018 82/550

# **Example: Fibonacci Sequence**

Hence, the solution is

$$\frac{1}{\sqrt{5}} \left[ \left( \frac{1+\sqrt{5}}{2} \right)^n - \left( \frac{1-\sqrt{5}}{2} \right)^n \right]$$

6.3 The Characteristic Polynomial

11. Apr. 2018 83/550

Consider the recurrence relation:

 $c_0 T(n) + c_1 T(n-1) + c_2 T(n-2) + \dots + c_k T(n-k) = f(n)$ with  $f(n) \neq 0$ .

While we have a fairly general technique for solving homogeneous, linear recurrence relations the inhomogeneous case is different.

The general solution of the recurrence relation is

 $T(n) = T_h(n) + T_p(n) ,$ 

where  $T_h$  is any solution to the homogeneous equation, and  $T_p$  is one particular solution to the inhomogeneous equation.

There is no general method to find a particular solution.

Example:

$$T[n] = T[n-1] + 1$$
  $T[0] = 1$ 

Then,

$$T[n-1] = T[n-2] + 1$$
  $(n \ge 2)$ 

Subtracting the first from the second equation gives,

$$T[n] - T[n-1] = T[n-1] - T[n-2] \qquad (n \ge 2)$$

or

$$T[n] = 2T[n-1] - T[n-2] \qquad (n \ge 2)$$

I get a completely determined recurrence if I add T[0] = 1 and T[1] = 2.

Example: Characteristic polynomial:

$$\underbrace{\lambda^2 - 2\lambda + 1}_{(\lambda - 1)^2} = 0$$

Then the solution is of the form

$$T[n] = \alpha 1^n + \beta n 1^n = \alpha + \beta n$$

T[0] = 1 gives  $\alpha = 1$ .

T[1] = 2 gives  $1 + \beta = 2 \Longrightarrow \beta = 1$ .

Ernst Mayr, Harald Räcke

6.3 The Characteristic Polynomial

11. Apr. 2018 87/550

If f(n) is a polynomial of degree r this method can be applied r + 1 times to obtain a homogeneous equation:

 $T[n] = T[n-1] + n^2$ 

Shift:

$$T[n-1] = T[n-2] + (n-1)^2 = T[n-2] + n^2 - 2n + 1$$

Difference:

$$T[n] - T[n-1] = T[n-1] - T[n-2] + 2n - 1$$

T[n] = 2T[n-1] - T[n-2] + 2n - 1

T[n] = 2T[n-1] - T[n-2] + 2n - 1

Shift:

$$T[n-1] = 2T[n-2] - T[n-3] + 2(n-1) - 1$$
$$= 2T[n-2] - T[n-3] + 2n - 3$$

Difference:

$$T[n] - T[n-1] = 2T[n-1] - T[n-2] + 2n - 1$$
$$- 2T[n-2] + T[n-3] - 2n + 3$$

$$T[n] = 3T[n-1] - 3T[n-2] + T[n-3] + 2$$

and so on...

#### **Definition 7 (Generating Function)**

Let  $(a_n)_{n\geq 0}$  be a sequence. The corresponding

generating function (Erzeugendenfunktion) is

$$F(z) := \sum_{n \ge 0} a_n z^n;$$

 exponential generating function (exponentielle Erzeugendenfunktion) is

$$F(z) := \sum_{n \ge 0} \frac{a_n}{n!} z^n.$$

6.4 Generating Functions

11. Apr. 2018 90/550

#### Example 8

1. The generating function of the sequence  $(1,0,0,\ldots)$  is

 $F(z)=1\,.$ 

**2.** The generating function of the sequence (1, 1, 1, ...) is

$$F(z)=\frac{1}{1-z}\,.$$

6.4 Generating Functions

11. Apr. 2018 91/550

There are two different views:

A generating function is a formal power series (formale Potenzreihe).

Then the generating function is an algebraic object.

Let  $f = \sum_{n\geq 0} a_n z^n$  and  $g = \sum_{n\geq 0} b_n z^n$ .

- Equality: f and g are equal if  $a_n = b_n$  for all n.
- Addition:  $f + g := \sum_{n \ge 0} (a_n + b_n) z^n$ .
- Multiplication:  $f \cdot g := \sum_{n \ge 0} c_n z^n$  with  $c_n = \sum_{p=0}^n a_p b_{n-p}$ .

There are no convergence issues here.

The arithmetic view:

We view a power series as a function  $f : \mathbb{C} \to \mathbb{C}$ .

Then, it is important to think about convergence/convergence radius etc.

6.4 Generating Functions

11. Apr. 2018 93/550

What does  $\sum_{n\geq 0} z^n = \frac{1}{1-z}$  mean in the algebraic view?

It means that the power series 1 - z and the power series  $\sum_{n \ge 0} z^n$  are invers, i.e.,

$$(1-z)\cdot \left(\sum_{n\geq 0}^{\infty}z^n\right)=1$$
.

This is well-defined.

6.4 Generating Functions

11. Apr. 2018 94/550

Suppose we are given the generating function

$$\sum_{n\geq 0} z^n = \frac{1}{1-z}$$

Formally the derivative of a formal power series  $\sum_{n\geq 0} a_n z^n$  is defined as  $\sum_{n\geq 0} na_n z^{n-1}$ .

The known rules for differentiation work for this definition. In particular, e.g. the derivative of  $\frac{1}{1-z}$  is  $\frac{1}{(1-z)^2}$ .

Note that this requires a proof if we consider power series as algebraic objects. However, we did not prove this in the lecture.

We can compute the derivative:

$$\underbrace{\sum_{n \ge 1} n z^{n-1}}_{\sum_{n > 0} (n+1) z^n} = \frac{1}{(1-z)^2}$$

Hence, the generating function of the sequence  $a_n = n + 1$  is  $1/(1-z)^2$ .

We can repeat this

$$\sum_{n\geq 0} (n+1)z^n = \frac{1}{(1-z)^2} \; .$$

Derivative:  

$$\sum_{\substack{n \ge 1 \\ \sum_{n > 0} (n+1)(n+2)z^n}} n(n+1)z^{n-1} = \frac{2}{(1-z)^3}$$

Hence, the generating function of the sequence  $a_n = (n+1)(n+2)$  is  $\frac{2}{(1-z)^3}$ .

6.4 Generating Functions

11. Apr. 2018 96/550

Computing the *k*-th derivative of  $\sum z^n$ .

$$\sum_{n \ge k} n(n-1) \cdot \ldots \cdot (n-k+1) z^{n-k} = \sum_{n \ge 0} (n+k) \cdot \ldots \cdot (n+1) z^n$$
$$= \frac{k!}{(1-z)^{k+1}} .$$

Hence:

$$\sum_{n\geq 0} \binom{n+k}{k} z^n = \frac{1}{(1-z)^{k+1}} \ .$$

The generating function of the sequence  $a_n = \binom{n+k}{k}$  is  $\frac{1}{(1-z)^{k+1}}$ .

6.4 Generating Functions

11. Apr. 2018 97/550

$$\sum_{n \ge 0} nz^n = \sum_{n \ge 0} (n+1)z^n - \sum_{n \ge 0} z^n$$
$$= \frac{1}{(1-z)^2} - \frac{1}{1-z}$$
$$= \frac{z}{(1-z)^2}$$

The generating function of the sequence  $a_n = n$  is  $\frac{z}{(1-z)^2}$ .

6.4 Generating Functions

11. Apr. 2018 98/550

We know

$$\sum_{n\geq 0} \mathcal{Y}^n = \frac{1}{1-\mathcal{Y}}$$

Hence,

$$\sum_{n\ge 0}a^nz^n=\frac{1}{1-az}$$

The generating function of the sequence  $f_n = a^n$  is  $\frac{1}{1-az}$ .

6.4 Generating Functions

11. Apr. 2018 99/550

#### Example: $a_n = a_{n-1} + 1$ , $a_0 = 1$

Suppose we have the recurrence  $a_n = a_{n-1} + 1$  for  $n \ge 1$  and  $a_0 = 1$ .

$$A(z) = \sum_{n \ge 0} a_n z^n$$
  
=  $a_0 + \sum_{n \ge 1} (a_{n-1} + 1) z^n$   
=  $1 + z \sum_{n \ge 1} a_{n-1} z^{n-1} + \sum_{n \ge 1} z^n$   
=  $z \sum_{n \ge 0} a_n z^n + \sum_{n \ge 0} z^n$   
=  $zA(z) + \sum_{n \ge 0} z^n$   
=  $zA(z) + \frac{1}{1-z}$ 

6.4 Generating Functions

11. Apr. 2018 100/550 Example:  $a_n = a_{n-1} + 1$ ,  $a_0 = 1$ 

Solving for A(z) gives

$$\sum_{n \ge 0} a_n z^n = A(z) = \frac{1}{(1-z)^2} = \sum_{n \ge 0} (n+1) z^n$$

Hence,  $a_n = n + 1$ .

6.4 Generating Functions

11. Apr. 2018 101/550

# Solving Recursions with Generating Functions

**1.** Set  $A(z) = \sum_{n \ge 0} a_n z^n$ .

- 2. Transform the right hand side so that boundary condition and recurrence relation can be plugged in.
- **3.** Do further transformations so that the infinite sums on the right hand side can be replaced by A(z).
- 4. Solving for A(z) gives an equation of the form A(z) = f(z), where hopefully f(z) is a simple function.
- 5. Write f(z) as a formal power series. Techniques:
  - partial fraction decomposition (Partialbruchzerlegung)
  - Iookup in tables
- **6.** The coefficients of the resulting power series are the  $a_n$ .

1. Set up generating function:

$$A(z) = \sum_{n \ge 0} a_n z^n$$

**2.** Transform right hand side so that recurrence can be plugged in:

$$A(z) = a_0 + \sum_{n \ge 1} a_n z^n$$

2. Plug in:

$$A(z) = 1 + \sum_{n \ge 1} (2a_{n-1})z^n$$

6.4 Generating Functions

11. Apr. 2018 105/550

**3.** Transform right hand side so that infinite sums can be replaced by A(z) or by simple function.

$$A(z) = 1 + \sum_{n \ge 1} (2a_{n-1})z^n$$
  
= 1 + 2z  $\sum_{n \ge 1} a_{n-1}z^{n-1}$   
= 1 + 2z  $\sum_{n \ge 0} a_n z^n$   
= 1 + 2z  $\cdot A(z)$ 

**4.** Solve for A(z).

$$A(z) = \frac{1}{1 - 2z}$$

6.4 Generating Functions

11. Apr. 2018 106/550

**5.** Rewrite f(z) as a power series:

$$\sum_{n\ge 0} a_n z^n = A(z) = \frac{1}{1-2z} = \sum_{n\ge 0} 2^n z^n$$

6.4 Generating Functions

11. Apr. 2018 107/550

1. Set up generating function:

$$A(z) = \sum_{n \ge 0} a_n z^n$$

6.4 Generating Functions

11. Apr. 2018 108/550

2./3. Transform right hand side:

A

$$\begin{aligned} &(z) = \sum_{n \ge 0} a_n z^n \\ &= a_0 + \sum_{n \ge 1} a_n z^n \\ &= 1 + \sum_{n \ge 1} (3a_{n-1} + n) z^n \\ &= 1 + 3z \sum_{n \ge 1} a_{n-1} z^{n-1} + \sum_{n \ge 1} n z^n \\ &= 1 + 3z \sum_{n \ge 0} a_n z^n + \sum_{n \ge 0} n z^n \\ &= 1 + 3z A(z) + \frac{z}{(1-z)^2} \end{aligned}$$

6.4 Generating Functions

11. Apr. 2018 109/550

**4.** Solve for A(z):

$$A(z) = 1 + 3zA(z) + \frac{z}{(1-z)^2}$$

gives

$$A(z) = \frac{(1-z)^2 + z}{(1-3z)(1-z)^2} = \frac{z^2 - z + 1}{(1-3z)(1-z)^2}$$

6.4 Generating Functions

11. Apr. 2018 110/550

**5.** Write f(z) as a formal power series:

We use partial fraction decomposition:

$$\frac{z^2 - z + 1}{(1 - 3z)(1 - z)^2} \stackrel{!}{=} \frac{A}{1 - 3z} + \frac{B}{1 - z} + \frac{C}{(1 - z)^2}$$

This gives

$$z^{2} - z + 1 = A(1 - z)^{2} + B(1 - 3z)(1 - z) + C(1 - 3z)$$
$$= A(1 - 2z + z^{2}) + B(1 - 4z + 3z^{2}) + C(1 - 3z)$$
$$= (A + 3B)z^{2} + (-2A - 4B - 3C)z + (A + B + C)$$

6.4 Generating Functions

11. Apr. 2018 111/550

**5.** Write f(z) as a formal power series:

This leads to the following conditions:

A + B + C = 12A + 4B + 3C = 1A + 3B = 1

which gives

$$A = \frac{7}{4}$$
  $B = -\frac{1}{4}$   $C = -\frac{1}{2}$ 

6.4 Generating Functions

11. Apr. 2018 112/550

**5.** Write f(z) as a formal power series:

$$\begin{aligned} A(z) &= \frac{7}{4} \cdot \frac{1}{1 - 3z} - \frac{1}{4} \cdot \frac{1}{1 - z} - \frac{1}{2} \cdot \frac{1}{(1 - z)^2} \\ &= \frac{7}{4} \cdot \sum_{n \ge 0} 3^n z^n - \frac{1}{4} \cdot \sum_{n \ge 0} z^n - \frac{1}{2} \cdot \sum_{n \ge 0} (n + 1) z^n \\ &= \sum_{n \ge 0} \left( \frac{7}{4} \cdot 3^n - \frac{1}{4} - \frac{1}{2} (n + 1) \right) z^n \\ &= \sum_{n \ge 0} \left( \frac{7}{4} \cdot 3^n - \frac{1}{2} n - \frac{3}{4} \right) z^n \end{aligned}$$

6. This means  $a_n = \frac{7}{4}3^n - \frac{1}{2}n - \frac{3}{4}$ .

Ernst Mayr, Harald Räcke

6.4 Generating Functions

11. Apr. 2018 113/550

## 6.5 Transformation of the Recurrence

#### Example 9

$$egin{aligned} f_0 &= 1 \ f_1 &= 2 \ f_n &= f_{n-1} \cdot f_{n-2} \mbox{ for } n \geq 2 \ . \end{aligned}$$

#### Define

 $g_n := \log f_n$ .

Then

$$g_n = g_{n-1} + g_{n-2}$$
 for  $n \ge 2$   
 $g_1 = \log 2 = 1$ (for  $\log = \log_2$ ),  $g_0 = 0$   
 $g_n = F_n$  (*n*-th Fibonacci number)  
 $f_n = 2^{F_n}$ 

11. Apr. 2018 114/550

## 6.5 Transformation of the Recurrence

#### Example 10

$$f_1 = 1$$
  
 $f_n = 3f_{\frac{n}{2}} + n$ ; for  $n = 2^k$ ,  $k \ge 1$ ;

#### Define

$$g_k := f_{2^k}$$
 .

#### Then:

$$g_0 = 1$$
  
 $g_k = 3g_{k-1} + 2^k, \ k \ge 1$ 

Ernst Mayr, Harald Räcke

6.5 Transformation of the Recurrence

11. Apr. 2018 115/550

### **6** Recurrences

We get

$$g_{k} = 3 [g_{k-1}] + 2^{k}$$

$$= 3 [3g_{k-2} + 2^{k-1}] + 2^{k}$$

$$= 3^{2} [g_{k-2}] + 32^{k-1} + 2^{k}$$

$$= 3^{2} [3g_{k-3} + 2^{k-2}] + 32^{k-1} + 2^{k}$$

$$= 3^{3}g_{k-3} + 3^{2}2^{k-2} + 32^{k-1} + 2^{k}$$

$$= 2^{k} \cdot \sum_{i=0}^{k} \left(\frac{3}{2}\right)^{i}$$

$$= 2^{k} \cdot \frac{\left(\frac{3}{2}\right)^{k+1} - 1}{\frac{1}{2}} = 3^{k+1} - 2^{k+1}$$

Ernst Mayr, Harald Räcke

6.5 Transformation of the Recurrence

11. Apr. 2018 116/550

## **6** Recurrences

Let  $n = 2^k$ :

$$g_k = 3^{k+1} - 2^{k+1}, \text{ hence}$$
  

$$f_n = 3 \cdot 3^k - 2 \cdot 2^k$$
  

$$= 3(2^{\log 3})^k - 2 \cdot 2^k$$
  

$$= 3(2^k)^{\log 3} - 2 \cdot 2^k$$
  

$$= 3n^{\log 3} - 2n .$$

## Part III

## **Data Structures**

11. Apr. 2018 118/550

## **Abstract Data Type**

An abstract data type (ADT) is defined by an interface of operations or methods that can be performed and that have a defined behavior.

The data types in this lecture all operate on objects that are represented by a [key, value] pair.

- The key comes from a totally ordered set, and we assume that there is an efficient comparison function.
- The value can be anything; it usually carries satellite information important for the application that uses the ADT.

## **Dynamic Set Operations**

- S. search(k): Returns pointer to object x from S with key[x] = k or null.
- S. insert(x): Inserts object x into set S. key[x] must not currently exist in the data-structure.
- S. delete(x): Given pointer to object x from S, delete x from the set.
- S. minimum(): Return pointer to object with smallest key-value in S.
- S. maximum(): Return pointer to object with largest key-value in S.
- S. successor(x): Return pointer to the next larger element in S or null if x is maximum.
- S. predecessor(x): Return pointer to the next smaller element in S or null if x is minimum.

## **Dynamic Set Operations**

- S. union(S'): Sets  $S := S \cup S'$ . The set S' is destroyed.
- S. merge(S'): Sets  $S := S \cup S'$ . Requires  $S \cap S' = \emptyset$ .
- ► S. split(k, S'):  $S := \{x \in S \mid \text{key}[x] \le k\}, S' := \{x \in S \mid \text{key}[x] > k\}.$
- S. concatenate(S'): S := S ∪ S'.
   Requires key[S. maximum()] ≤ key[S'. minimum()].
- S. decrease-key(x, k): Replace key[x] by  $k \le key[x]$ .

## **Examples of ADTs**

#### Stack:

- S. push(x): Insert an element.
- S. pop(): Return the element from S that was inserted most recently; delete it from S.
- S. empty(): Tell if S contains any object.

#### Queue:

- S. enqueue(x): Insert an element.
- S. dequeue(): Return the element that is longest in the structure; delete it from S.
- S. empty(): Tell if S contains any object.

#### Priority-Queue:

- S. insert(x): Insert an element.
- S. delete-min(): Return the element with lowest key-value; delete it from S.

## 7 Dictionary

#### Dictionary:

- S. insert(x): Insert an element x.
- ► *S*. delete(*x*): Delete the element pointed to by *x*.
- S. search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

7 Dictionary

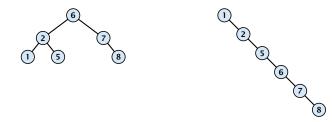

11. Apr. 2018 123/550

## 7.1 Binary Search Trees

An (internal) binary search tree stores the elements in a binary tree. Each tree-node corresponds to an element. All elements in the left sub-tree of a node v have a smaller key-value than key[v] and elements in the right sub-tree have a larger-key value. We assume that all key-values are different.

(External Search Trees store objects only at leaf-vertices)

Examples:

7.1 Binary Search Trees

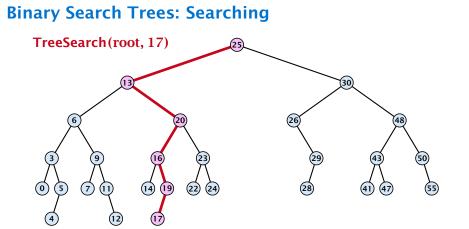

11. Apr. 2018 124/550

## 7.1 Binary Search Trees

We consider the following operations on binary search trees. Note that this is a super-set of the dictionary-operations.

- T. insert(x)
- ► T. delete(x)
- ► T. search(k)
- ► T. successor(x)
- ► T. predecessor(x)
- ► T. minimum()
- T. maximum()

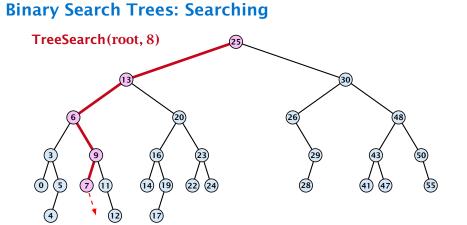

#### **Algorithm 1** TreeSearch(*x*, *k*)

- 1: if x = null or k = key[x] return x
- 2: **if** k < key[x] **return** TreeSearch(left[x], k)
- 3: **else return** TreeSearch(right[*x*], *k*)

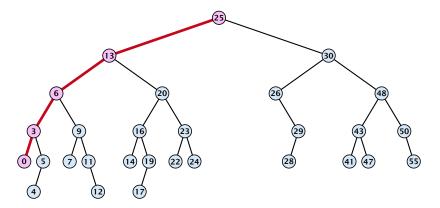

#### Algorithm 1 TreeSearch(x, k)

- 1: if x = null or k = key[x] return x
- 2: if k < key[x] return TreeSearch(left[x], k)
- 3: **else return** TreeSearch(right[*x*], *k*)

## **Binary Search Trees: Minimum**

#### **Algorithm 2** TreeMin(*x*)

- 1: if x = null or left[x] = null return x
- 2: **return** TreeMin(left[x])

## **Binary Search Trees: Delete**

#### Case 1:

Element does not have any children

Simply go to the parent and set the corresponding pointer to null.

# **Binary Search Trees: Delete** $\bigcirc$ 5 7 (22) (14) 19) (24)

#### Case 2:

Element has exactly one child

Splice the element out of the tree by connecting its parent to its successor.

# **Binary Search Trees: Delete** $\bigcirc$ 5 7 (22) (14) 19 (24) 20

#### Case 3:

#### Element has two children

- Find the successor of the element
- Splice successor out of the tree
- Replace content of element by content of successor

## **Binary Search Trees: Delete**

```
Algorithm 9 TreeDelete(z)
 1: if left[z] = null or right[z] = null
           then \gamma \leftarrow z else \gamma \leftarrow TreeSucc(z); select \gamma to splice out
 2.
 3: if left[\gamma] \neq null
           then x \leftarrow \text{left}[\gamma] else x \leftarrow \text{right}[\gamma]; x is child of \gamma (or null)
 4:
 5: if x \neq null then parent[x] \leftarrow parent[y]; parent[x] is correct
 6: if parent[\gamma] = null then
 7: \operatorname{root}[T] \leftarrow x
 8: else
    if \gamma = \text{left}[\text{parent}[\gamma]] then
                                                                     fix pointer to x
 9:
10:
                 left[parent[\gamma]] \leftarrow x
11: else
12:
         right[parent[\gamma]] \leftarrow x
13: if \gamma \neq z then copy \gamma-data to z
```

## **Balanced Binary Search Trees**

All operations on a binary search tree can be performed in time O(h), where h denotes the height of the tree.

However the height of the tree may become as large as  $\Theta(n)$ .

#### **Balanced Binary Search Trees**

With each insert- and delete-operation perform local adjustments to guarantee a height of  $O(\log n)$ .

AVL-trees, Red-black trees, Scapegoat trees, 2-3 trees, B-trees, AA trees, Treaps

similar: SPLAY trees.

Binary search trees can be found in every standard text book. For example Chapter 7.1 in [MS08] and Chapter 12 in [CLRS90].

7.1 Binary Search Trees

11. Apr. 2018 134/550

## 7.2 Red Black Trees

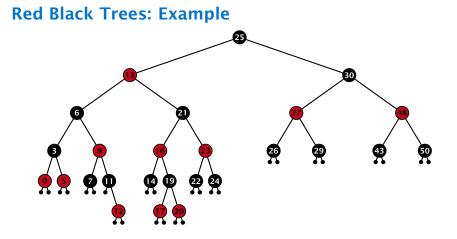

#### **Definition 11**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- **3.** For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data

7.2 Red Black Trees

11. Apr. 2018 135/550

#### Lemma 12

A red-black tree with n internal nodes has height at most  $\mathcal{O}(\log n)$ .

#### **Definition 13**

The black height bh(v) of a node v in a red black tree is the number of black nodes on a path from v to a leaf vertex (not counting v).

We first show:

#### Lemma 14

A sub-tree of black height bh(v) in a red black tree contains at least  $2^{bh(v)} - 1$  internal vertices.

#### Proof of Lemma 14.

Induction on the height of *v*.

**base case (height**(v) = 0)

- If height(v) (maximum distance btw. v and a node in the sub-tree rooted at v) is 0 then v is a leaf.
- The black height of v is 0.
- ► The sub-tree rooted at v contains  $0 = 2^{bh(v)} 1$  inner vertices.

7.2 Red Black Trees

11. Apr. 2018 137/550

#### Proof (cont.)

#### induction step

- Supose v is a node with height(v) > 0.
- $\triangleright$  v has two children with strictly smaller height.
- These children (c<sub>1</sub>, c<sub>2</sub>) either have bh(c<sub>i</sub>) = bh(v) or bh(c<sub>i</sub>) = bh(v) 1.
- ▶ By induction hypothesis both sub-trees contain at least  $2^{bh(v)-1} 1$  internal vertices.
- ► Then  $T_v$  contains at least  $2(2^{bh(v)-1} 1) + 1 \ge 2^{bh(v)} 1$  vertices.

7.2 Red Black Trees

11. Apr. 2018 138/550

#### Proof of Lemma 12.

Let h denote the height of the red-black tree, and let P denote a path from the root to the furthest leaf.

At least half of the node on P must be black, since a red node must be followed by a black node.

Hence, the black height of the root is at least h/2.

The tree contains at least  $2^{h/2} - 1$  internal vertices. Hence,  $2^{h/2} - 1 \le n$ .

Hence,  $h \leq 2\log(n+1) = \mathcal{O}(\log n)$ .

#### **Definition 1**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- **3.** For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data.

We need to adapt the insert and delete operations so that the red black properties are maintained.

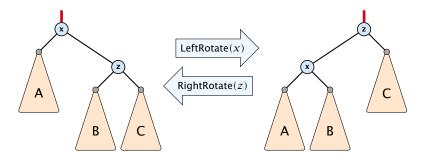

7.2 Red Black Trees

11. Apr. 2018 141/550

### **Rotations**

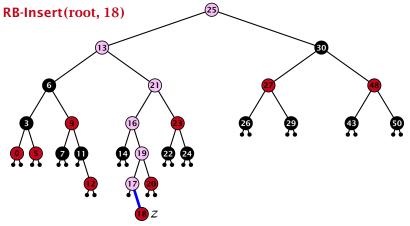

The properties will be maintained through rotations:

7.2 Red Black Trees

11. Apr. 2018 142/550

#### Insert:

- first make a normal insert into a binary search tree
- then fix red-black properties

Ernst Mayr, Harald Räcke

7.2 Red Black Trees

11. Apr. 2018 143/550

#### Invariant of the fix-up algorithm:

- z is a red node
- the black-height property is fulfilled at every node
- the only violation of red-black properties occurs at z and parent[z]
  - either both of them are red (most important case)
  - or the parent does not exist (violation since root must be black)

If z has a parent but no grand-parent we could simply color the parent/root black; however this case never happens.

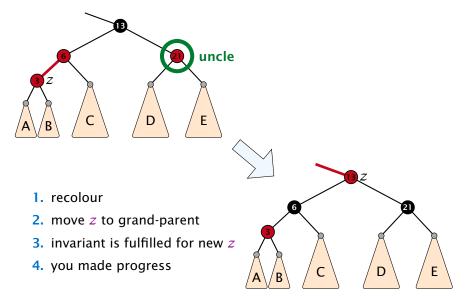

Algorithm 10 InsertFix( <i>z</i> )	
1: while $parent[z] \neq null$ and $col[parent[z]] = red$ do	
2: <b>if</b> parent[ $z$ ] = left[gp[ $z$ ]] <b>then</b> $z$ in left subtree of grandparent	
3: $uncle \leftarrow right[grandparent[z]]$	
4: <b>if</b> col[ <i>uncle</i> ] = red <b>then</b>	Case 1: uncle red
5: $\operatorname{col}[p[z]] \leftarrow \operatorname{black}; \operatorname{col}[u] \leftarrow \operatorname{black};$	
6: $\operatorname{col}[\operatorname{gp}[z]] \leftarrow \operatorname{red}; z \leftarrow \operatorname{grandparent}[z];$	
7: else	Case 2: uncle black
8: <b>if</b> $z = right[parent[z]]$ <b>then</b>	2a: <i>z</i> right child
9: $z \leftarrow p[z]; LeftRotate(z);$	
10: $\operatorname{col}[p[z]] \leftarrow \operatorname{black}; \operatorname{col}[\operatorname{gp}[z]] \leftarrow \operatorname{red}; \operatorname{2b:} z \operatorname{left} \operatorname{child}$	
11: RightRotate( $gp[z]$ );	
12: <b>else</b> same as then-clause but right and left exchanged	
13: $col(root[T]) \leftarrow black;$	

7.2 Red Black Trees

### Case 1: Red Uncle

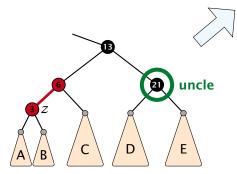

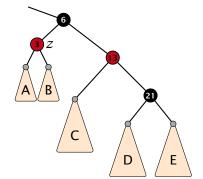

7.2 Red Black Trees

11. Apr. 2018 146/550

# Case 2b: Black uncle and z is left child

- 1. rotate around grandparent
- 2. re-colour to ensure that black height property holds
- 3. you have a red black tree

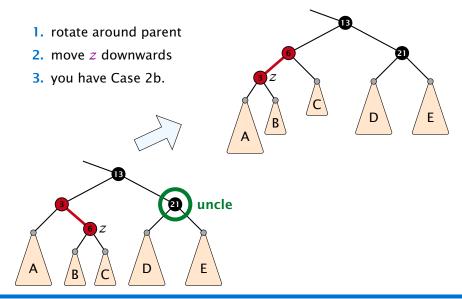

7.2 Red Black Trees

11. Apr. 2018 147/550

### Case 2a: Black uncle and z is right child

7.2 Red Black Trees

11. Apr. 2018 148/550

#### **Running time:**

- Only Case 1 may repeat; but only h/2 many steps, where h is the height of the tree.
- Case 2a → Case 2b → red-black tree
- Case 2b → red-black tree

Performing Case 1 at most  $O(\log n)$  times and every other case at most once, we get a red-black tree. Hence  $O(\log n)$ re-colorings and at most 2 rotations.

### **Red Black Trees: Delete**

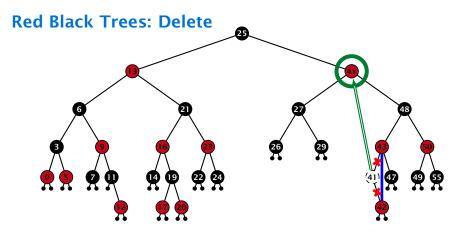

First do a standard delete.

If the spliced out node x was red everything is fine.

If it was black there may be the following problems.

- Parent and child of x were red; two adjacent red vertices.
- If you delete the root, the root may now be red.
- Every path from an ancestor of x to a descendant leaf of x changes the number of black nodes. Black height property might be violated.

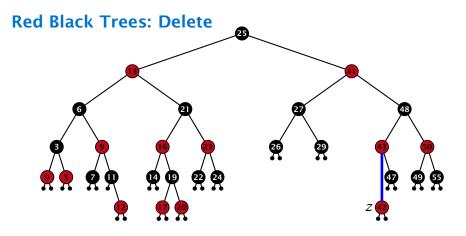

#### Case 3:

Element has two children

- do normal delete
- when replacing content by content of successor, don't change color of node

#### Delete:

- deleting black node messes up black-height property
- ▶ if *z* is red, we can simply color it black and everything is fine
- the problem is if z is black (e.g. a dummy-leaf); we call a fix-up procedure to fix the problem.

### **Red Black Trees: Delete**

#### Invariant of the fix-up algorithm

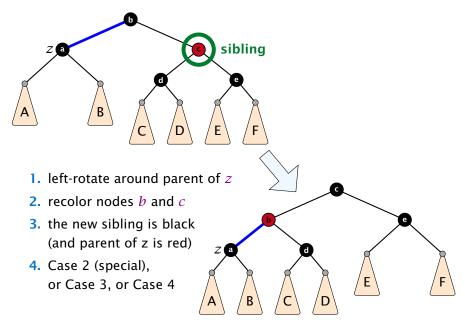

- the node z is black
- if we "assign" a fake black unit to the edge from z to its parent then the black-height property is fulfilled

**Goal:** make rotations in such a way that you at some point can remove the fake black unit from the edge.

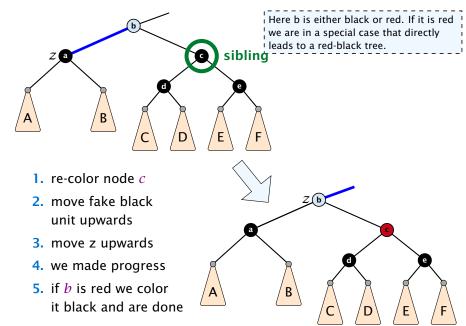

7.2 Red Black Trees

# Case 1: Sibling of z is red

# Case 2: Sibling is black with two black children

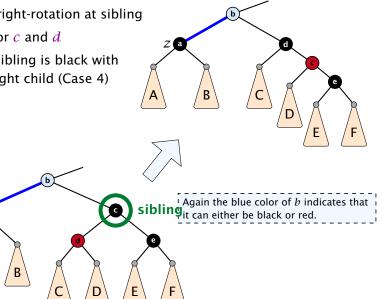

# Case 3: Sibling black with one black child to the right

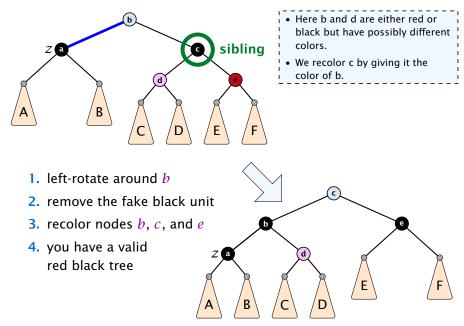

- 1. do a right-rotation at sibling
- 2. recolor c and d

A

3. new sibling is black with red right child (Case 4)

# Case 4: Sibling is black with red right child

#### Running time:

- only Case 2 can repeat; but only h many steps, where h is the height of the tree
- ► Case 1  $\rightarrow$  Case 2 (special)  $\rightarrow$  red black tree
  - Case 1  $\rightarrow$  Case 3  $\rightarrow$  Case 4  $\rightarrow$  red black tree
  - Case 1  $\rightarrow$  Case 4  $\rightarrow$  red black tree
- Case  $3 \rightarrow$  Case  $4 \rightarrow$  red black tree
- Case 4 → red black tree

Performing Case 2 at most  $O(\log n)$  times and every other step at most once, we get a red black tree. Hence,  $O(\log n)$ re-colorings and at most 3 rotations.

### **Red-Black Trees**

#### Bibliography

[CLRS90] Thomas H. Cormen, Charles E. Leiserson, Ron L. Rivest, Clifford Stein: Introduction to Algorithms (3rd ed.), MIT Press and McGraw-Hill, 2009

Red black trees are covered in detail in Chapter 13 of [CLRS90].

7.2 Red Black Trees

11. Apr. 2018 159/550

#### Disadvantage of balanced search trees:

- worst case; no advantage for easy inputs
- additional memory required
- complicated implementation

#### Splay Trees:

- after access, an element is moved to the root; splay(x)
   repeated accesses are faster
- only amortized guarantee
- read-operations change the tree

#### find(x)

- search for x according to a search tree
- let  $\bar{x}$  be last element on search-path
- splay( $\bar{x}$ )

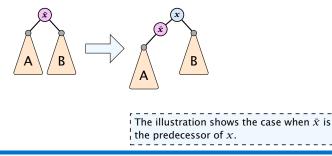

7.3 Splay Trees

11. Apr. 2018 160/550

#### insert(x)

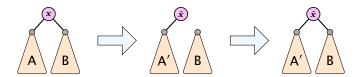

- search for x; x̄ is last visited element during search (successer or predecessor of x)
- splay( $\bar{x}$ ) moves  $\bar{x}$  to the root
- insert x as new root

#### delete(x)

- search for x; splay(x); remove x
- search largest element  $\bar{x}$  in A
- splay( $\bar{x}$ ) (on subtree A)
- connect root of *B* as right child of  $\bar{x}$

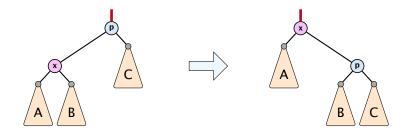

7.3 Splay Trees

11. Apr. 2018 162/550

#### **Move to Root**

#### How to bring element to root?

- one (bad) option: moveToRoot(x)
- iteratively do rotation around parent of x until x is root
- ▶ if *x* is left child do right rotation otw. left rotation

7.3 Splay Trees

11. Apr. 2018 163/550

### Splay: Zig Case

#### better option splay(x):

zig case: if x is child of root do left rotation or right rotation around parent

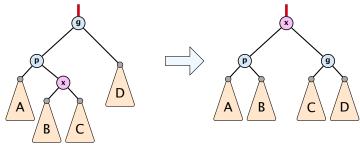

Note that moveToRoot(x) does the same.

11. Apr. 2018 164/550

# Splay: Zigzag Case

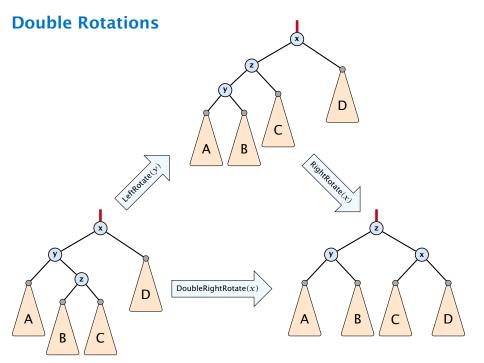

#### better option splay(x):

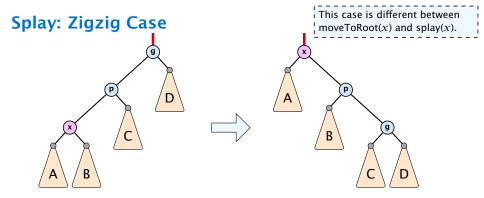

- zigzag case: if x is right child and parent of x is left child (or x left child parent of x right child)
- do double right rotation around grand-parent (resp. double left rotation)

Note that moveToRoot(x) does the same.

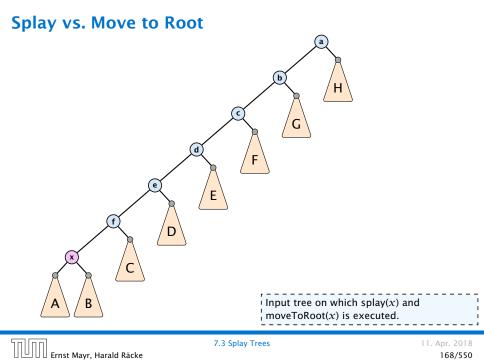

7.3 Splay Trees

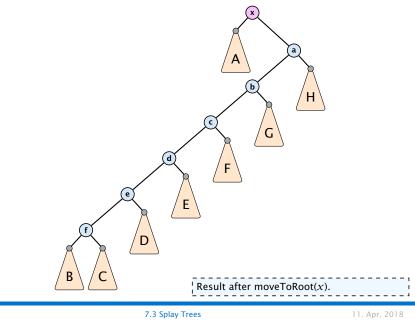

#### better option splay(x):

- zigzig case: if x is left child and parent of x is left child (or x right child, parent of x right child)
- do right roation around grand-parent followed by right rotation around parent (resp. left rotations)

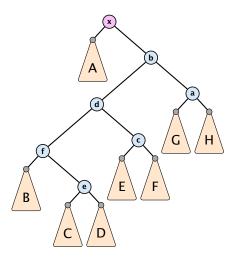

#### Splay vs. Move to Root

Ernst Mayr, Harald Räcke

168/550

#### Splay vs. Move to Root

# **Static Optimality**

Suppose we have a sequence of m find-operations. find(x) appears  $h_x$  times in this sequence.

The cost of a static search tree *T* is:

$$cost(T) = m + \sum_{x} h_x \operatorname{depth}_T(x)$$

The total cost for processing the sequence on a splay-tree is  $O(cost(T_{min}))$ , where  $T_{min}$  is an optimal static search tree.

 $depth_T(x)$  is the number of edges on a path from the root of T to x.

Theorem given without proof.

# **Dynamic Optimality**

Let S be a sequence with m find-operations.

Let *A* be a data-structure based on a search tree:

- the cost for accessing element x is 1 + depth(x);
- after accessing x the tree may be re-arranged through rotations;

#### **Conjecture:**

A splay tree that only contains elements from *S* has cost O(cost(A, S)), for processing *S*.

7.3 Splay Trees

11. Apr. 2018 171/550

#### Lemma 15

Splay Trees have an amortized running time of  $O(\log n)$  for all operations.

7.3 Splay Trees

11. Apr. 2018 172/550

# **Amortized Analysis**

#### **Definition 16**

A data structure with operations  $op_1(), \ldots, op_k()$  has amortized running times  $t_1, \ldots, t_k$  for these operations if the following holds.

Suppose you are given a sequence of operations (starting with an empty data-structure) that operate on at most n elements, and let  $k_i$  denote the number of occurences of  $op_i()$  within this sequence. Then the actual running time must be at most  $\sum_i k_i \cdot t_i(n)$ .

7.3 Splay Trees

### **Potential Method**

#### Introduce a potential for the data structure.

- $\Phi(D_i)$  is the potential after the *i*-th operation.
- Amortized cost of the *i*-th operation is

 $\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) \ . \label{eq:ci}$ 

Show that  $\Phi(D_i) \ge \Phi(D_0)$ .

Then

$$\sum_{i=1}^{k} c_i \le \sum_{i=1}^{k} c_i + \Phi(D_k) - \Phi(D_0) = \sum_{i=1}^{k} \hat{c}_i$$

This means the amortized costs can be used to derive a bound on the total cost.

7.3 Splay Trees

11. Apr. 2018 174/550

# **Example: Stack**

#### Stack

- ► S. push()
- ► S. pop()
- S. multipop(k): removes k items from the stack. If the stack currently contains less than k items it empties the stack.
- The user has to ensure that pop and multipop do not generate an underflow.

Actual cost:

- S. push(): cost 1.
- ► S. pop(): cost 1.
- ► *S*. multipop(*k*): cost min{size, *k*} = *k*.

### **Example: Stack**

Use potential function  $\Phi(S)$  = number of elements on the stack.

#### Amortized cost:

S. push(): cost

 $\hat{C}_{\text{push}} = C_{\text{push}} + \Delta \Phi = 1 + 1 \le 2$ .

S. pop(): cost

$$\hat{C}_{\rm pop} = C_{\rm pop} + \Delta \Phi = 1-1 \le 0$$
 .

Note that the analysis becomes wrong if pop() or multipop() are called on an empty stack.

► S. multipop(k): cost  $\hat{C}_{mp} = C_{mp} + \Delta \Phi = \min\{\text{size}, k\} - \min\{\text{size}, k\} \le 0$ .

החוחר	Ernst Mayr,		
	Ernst Mayr,	Harald	Räcke

# **Example: Binary Counter**

#### Incrementing a binary counter:

Consider a computational model where each bit-operation costs one time-unit.

Incrementing an n-bit binary counter may require to examine n-bits, and maybe change them.

#### Actual cost:

- Changing bit from 0 to 1: cost 1.
- Changing bit from 1 to 0: cost 1.
- Increment: cost is k + 1, where k is the number of consecutive ones in the least significant bit-positions (e.g, 001101 has k = 1).

#### **Example: Binary Counter**

Choose potential function  $\Phi(x) = k$ , where k denotes the number of ones in the binary representation of x.

#### Amortized cost:

Changing bit from 0 to 1:

$$\hat{C}_{0\to 1} = C_{0\to 1} + \Delta \Phi = 1 + 1 \le 2$$
.

• Changing bit from 1 to 0:

$$\hat{C}_{1\to 0} = C_{1\to 0} + \Delta \Phi = 1 - 1 \le 0$$
.

Increment: Let k denotes the number of consecutive ones in the least significant bit-positions. An increment involves k (1 → 0)-operations, and one (0 → 1)-operation.

Hence, the amortized cost is  $k\hat{C}_{1\rightarrow 0} + \hat{C}_{0\rightarrow 1} \leq 2$ .

# **Splay Trees**

#### potential function for splay trees:

- size  $\mathbf{s}(\mathbf{x}) = |T_{\mathbf{x}}|$
- rank  $r(x) = \log_2(s(x))$
- $\blacktriangleright \Phi(T) = \sum_{v \in T} r(v)$

amortized cost = real cost + potential change

The cost is essentially the cost of the splay-operation, which is 1 plus the number of rotations.

7.3 Splay Trees

11. Apr. 2018 179/550

# Splay: Zig Case

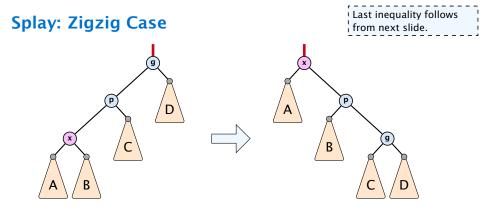

$$\Delta \Phi = r'(x) + r'(p) - r(x) - r(p)$$
$$= r'(p) - r(x)$$
$$\leq r'(x) - r(x)$$

$$\operatorname{cost}_{\operatorname{zig}} \le 1 + 3(r'(x) - r(x))$$

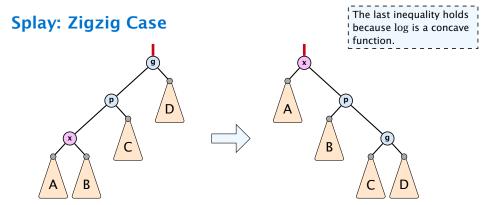

7.3 Splay Trees

11. Apr. 2018 180/550

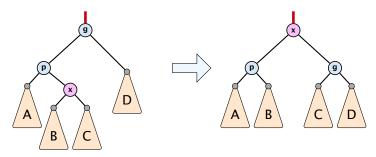

$$\begin{aligned} \Delta \Phi &= r'(x) + r'(p) + r'(g) - r(x) - r(p) - r(g) \\ &= r'(p) + r'(g) - r(x) - r(p) \\ &\leq r'(x) + r'(g) - r(x) - r(x) \\ &= r'(x) + r'(g) + r(x) - 3r'(x) + 3r'(x) - r(x) - 2r(x) \\ &= -2r'(x) + r'(g) + r(x) + 3(r'(x) - r(x)) \\ &\leq -2 + 3(r'(x) - r(x)) \Rightarrow \operatorname{cost_{zigzig}} \leq 3(r'(x) - r(x)) \end{aligned}$$

$$\frac{1}{2} \left( r(x) + r'(g) - 2r'(x) \right)$$
  
=  $\frac{1}{2} \left( \log(s(x)) + \log(s'(g)) - 2\log(s'(x)) \right)$   
=  $\frac{1}{2} \log \left( \frac{s(x)}{s'(x)} \right) + \frac{1}{2} \log \left( \frac{s'(g)}{s'(x)} \right)$   
 $\leq \log \left( \frac{1}{2} \frac{s(x)}{s'(x)} + \frac{1}{2} \frac{s'(g)}{s'(x)} \right) \leq \log \left( \frac{1}{2} \right) = -1$ 

# Splay: Zigzag Case

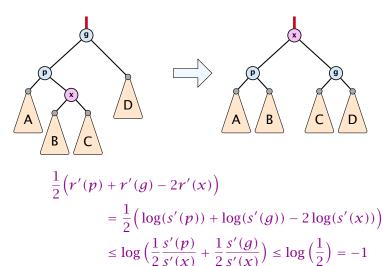

$$\begin{aligned} \Delta \Phi &= r'(x) + r'(p) + r'(g) - r(x) - r(p) - r(g) \\ &= r'(p) + r'(g) - r(x) - r(p) \\ &\leq r'(p) + r'(g) - r(x) - r(x) \\ &= r'(p) + r'(g) - 2r'(x) + 2r'(x) - 2r(x) \\ &\leq -2 + 2(r'(x) - r(x)) \quad \Rightarrow \operatorname{cost_{zigzag}} \leq 3(r'(x) - r(x)) \end{aligned}$$

7.3 Splay Trees

11. Apr. 2018 182/550

# Splay: Zigzag Case

7.3 Splay Trees

11. Apr. 2018 182/550 Amortized cost of the whole splay operation:

$$\leq 1 + 1 + \sum_{\text{steps } t} 3(r_t(x) - r_{t-1}(x))$$
$$= 2 + r(\text{root}) - r_0(x)$$
$$\leq \mathcal{O}(\log n)$$

The first one is added due to the fact that so far for each step of a splay-operation we have only counted the number of rotations, but the cost is 1+#rotations.

The second one comes from the zig-operation. Note that we have at most one zig-operation during a splay.

## **Splay Trees**

Bibliography

7.3 Splay Trees

11. Apr. 2018 184/550

Suppose you want to develop a data structure with:

- Insert(x): insert element x.
- Search(*k*): search for element with key *k*.
- Delete(x): delete element referenced by pointer x.
- Find-by-rank(ℓ): return the ℓ-th element; return "error" if the data-structure contains less than ℓ elements.

# Augment an existing data-structure instead of developing a new one.

#### How to augment a data-structure

- choose an underlying data-structure
- 2. determine additional information to be stored in the underlying structure
- 3. verify/show how the additional information can be maintained for the basic modifying operations on the underlying structure.
- 4. develop the new operations

 Of course, the above steps heavily depend on each other. For example it makes no sense to choose additional information to be stored (Step 2), and later realize that either the information cannot be maintained efficiently (Step 3) or is not sufficient to support the new operations (Step 4).

• However, the above outline is a good way to describe/document a new data-structure.

7.4 Augmenting Data Structures

# Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time $O(\log n)$ .

- 1. We choose a red-black tree as the underlying data-structure.
- **2.** We store in each node v the size of the sub-tree rooted at v.
- 3. We need to be able to update the size-field in each node without asymptotically affecting the running time of insert, delete, and search. We come back to this step later...

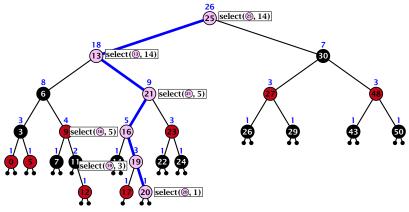

Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time  $O(\log n)$ .

4. How does find-by-rank work?Find-by-rank(k) = Select(root,k) with

Algorithm 11 Select(x, i)1: if x = null then return error2: if left[x]  $\neq$  null then  $r \leftarrow$  left[x].size +1 else  $r \leftarrow$  13: if i = r then return x4: if i < r then5: return Select(left[x], i)6: else7: return Select(right[x], i - r)

# Select(x, i)

#### Find-by-rank:

- decide whether you have to proceed into the left or right sub-tree
- adjust the rank that you are searching for if you go right

7.4 Augmenting Data Structures

Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time  $O(\log n)$ .

3. How do we maintain information?

Search(k): Nothing to do.

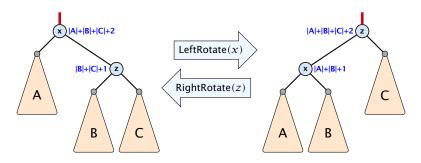

**Insert**(x): When going down the search path increase the size field for each visited node. Maintain the size field during rotations.

**Delete**(x): Directly after splicing out a node traverse the path from the spliced out node upwards, and decrease the size counter on every node on this path. Maintain the size field during rotations.

#### Rotations

The only operation during the fix-up procedure that alters the tree and requires an update of the size-field:

The nodes x and z are the only nodes changing their size-fields.

The new size-fields can be computed locally from the size-fields of the children.

#### Bibliography

See Chapter 14 of [CLRS90].

7.4 Augmenting Data Structures

11. Apr. 2018 191/550

#### **Definition 17**

For  $b \ge 2a - 1$  an (a, b)-tree is a search tree with the following properties

- 1. all leaves have the same distance to the root
- every internal non-root vertex v has at least a and at most
   b children
- 3. the root has degree at least 2 if the tree is non-empty
- 4. the internal vertices do not contain data, but only keys (external search tree)
- 5. there is a special dummy leaf node with key-value  $\infty$

Each internal node v with d(v) children stores d-1 keys  $k_1, \ldots, k_{d-1}$ . The *i*-th subtree of v fulfills

 $k_{i-1} < ext{ key in } i ext{-th sub-tree } \leq k_i$  ,

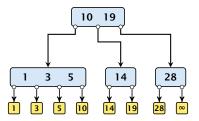

where we use  $k_0 = -\infty$  and  $k_d = \infty$ .

7.5 (*a*, *b*)-trees

11. Apr. 2018 192/550

#### Example 18

7.5 (*a*, *b*)-trees

11. Apr. 2018 193/550

#### Variants

- The dummy leaf element may not exist; it only makes implementation more convenient.
- Variants in which b = 2a are commonly referred to as B-trees.
- A B-tree usually refers to the variant in which keys and data are stored at internal nodes.
- A B<sup>+</sup> tree stores the data only at leaf nodes as in our definition. Sometimes the leaf nodes are also connected in a linear list data structure to speed up the computation of successors and predecessors.
- A B\* tree requires that a node is at least 2/3-full as opposed to 1/2-full (the requirement of a B-tree).

7.5 (*a*, *b*)-trees

#### Lemma 19

Let T be an (a, b)-tree for n > 0 elements (i.e., n + 1 leaf nodes) and height h (number of edges from root to a leaf vertex). Then

- 1.  $2a^{h-1} \le n+1 \le b^h$
- **2.**  $\log_b(n+1) \le h \le 1 + \log_a(\frac{n+1}{2})$

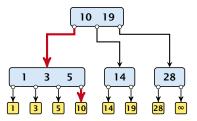

#### Proof.

- If n > 0 the root has degree at least 2 and all other nodes have degree at least a. This gives that the number of leaf nodes is at least 2a<sup>h-1</sup>.
- Analogously, the degree of any node is at most b and, hence, the number of leaf nodes at most b<sup>h</sup>.

### Search

Search(8)

The search is straightforward. It is only important that you need to go all the way to the leaf.

Time:  $O(b \cdot h) = O(b \cdot \log n)$ , if the individual nodes are organized as linear lists.

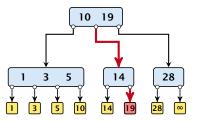

7.5 (*a*, *b*)-trees

11. Apr. 2018 196/550

#### Search

Search(19)

The search is straightforward. It is only important that you need to go all the way to the leaf.

Time:  $O(b \cdot h) = O(b \cdot \log n)$ , if the individual nodes are organized as linear lists.

7.5 (*a*, *b*)-trees

11. Apr. 2018 196/550

Insert element x:

- Follow the path as if searching for key[x].
- If this search ends in leaf  $\ell$ , insert x before this leaf.
- For this add key[x] to the key-list of the last internal node v on the path.
- If after the insert v contains b nodes, do Rebalance(v).

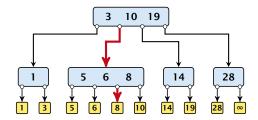

7.5 (*a*, *b*)-trees

#### Rebalance(v):

- Let  $k_i$ , i = 1, ..., b denote the keys stored in v.
- Let  $j := \lfloor \frac{b+1}{2} \rfloor$  be the middle element.
- Create two nodes v<sub>1</sub>, and v<sub>2</sub>. v<sub>1</sub> gets all keys k<sub>1</sub>,..., k<sub>j-1</sub> and v<sub>2</sub> gets keys k<sub>j+1</sub>,..., k<sub>b</sub>.
- ▶ Both nodes get at least  $\lfloor \frac{b-1}{2} \rfloor$  keys, and have therefore degree at least  $\lfloor \frac{b-1}{2} \rfloor + 1 \ge a$  since  $b \ge 2a 1$ .
- They get at most [<sup>b-1</sup>/<sub>2</sub>] keys, and have therefore degree at most [<sup>b-1</sup>/<sub>2</sub>] + 1 ≤ b (since b ≥ 2).
- The key k<sub>j</sub> is promoted to the parent of v. The current pointer to v is altered to point to v<sub>1</sub>, and a new pointer (to the right of k<sub>j</sub>) in the parent is added to point to v<sub>2</sub>.
- Then, re-balance the parent.

#### Delete

Delete element *x* (pointer to leaf vertex):

- Let v denote the parent of x. If key[x] is contained in v, remove the key from v, and delete the leaf vertex.
- Otherwise delete the key of the predecessor of x from v; delete the leaf vertex; and replace the occurrence of key[x] in internal nodes by the predecessor key. (Note that it appears in exactly one internal vertex).
- ► If now the number of keys in v is below a 1 perform Rebalance'(v).

7.5 (*a*, *b*)-trees

## Delete

#### Rebalance'(v):

- If there is a neighbour of v that has at least a keys take over the largest (if right neighbor) or smallest (if left neighbour) and the corresponding sub-tree.
- If not: merge v with one of its neighbours.
- The merged node contains at most (a − 2) + (a − 1) + 1 keys, and has therefore at most 2a − 1 ≤ b successors.
- Then rebalance the parent.
- During this process the root may become empty. In this case the root is deleted and the height of the tree decreases.

7.5 (*a*, *b*)-trees

#### Delete

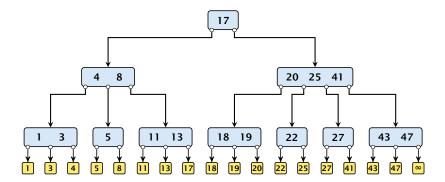

Animation for deleting in an (a, b)-tree is only available in the lecture version of the slides.

Why do we not use a list for implementing the ADT Dynamic Set?

- time for search  $\Theta(n)$
- time for insert  $\Theta(n)$  (dominated by searching the item)
- ► time for delete Θ(1) if we are given a handle to the object, otw. Θ(n)

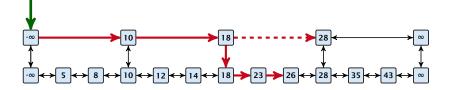

7.6 Skip Lists

11. Apr. 2018 204/550

How can we improve the search-operation?

#### Add an express lane:

Let  $|L_1|$  denote the number of elements in the "express lane", and  $|L_0| = n$  the number of all elements (ignoring dummy elements).

Worst case search time:  $|L_1| + \frac{|L_0|}{|L_1|}$  (ignoring additive constants)

Choose  $|L_1| = \sqrt{n}$ . Then search time  $\Theta(\sqrt{n})$ .

Add more express lanes. Lane  $L_i$  contains roughly every  $\frac{L_{i-1}}{L_i}$ -th item from list  $L_{i-1}$ .

#### Search(x) (k + 1 lists $L_0, \ldots, L_k$ )

- Find the largest item in list L<sub>k</sub> that is smaller than x. At most |L<sub>k</sub>| + 2 steps.
- Find the largest item in list  $L_{k-1}$  that is smaller than x. At most  $\left\lfloor \frac{|L_{k-1}|}{|L_{k}|+1} \right\rfloor + 2$  steps.
- Find the largest item in list  $L_{k-2}$  that is smaller than x. At most  $\left[\frac{|L_{k-2}|}{|L_{k-1}|+1}\right] + 2$  steps.

• At most 
$$|L_k| + \sum_{i=1}^k \frac{L_{i-1}}{L_i} + 3(k+1)$$
 steps.

Choose ratios between list-lengths evenly, i.e.,  $\frac{|L_{i-1}|}{|L_i|} = r$ , and, hence,  $L_k \approx r^{-k}n$ .

Worst case running time is:  $\mathcal{O}(r^{-k}n + kr)$ . Choose  $r = n^{\frac{1}{k+1}}$ . Then

$$r^{-k}n + kr = \left(n^{\frac{1}{k+1}}\right)^{-k}n + kn^{\frac{1}{k+1}}$$
$$= n^{1-\frac{k}{k+1}} + kn^{\frac{1}{k+1}}$$
$$= (k+1)n^{\frac{1}{k+1}} .$$

Choosing  $k = \Theta(\log n)$  gives a logarithmic running time.

7.6 Skip Lists

#### How to do insert and delete?

If we want that in L<sub>i</sub> we always skip over roughly the same number of elements in L<sub>i-1</sub> an insert or delete may require a lot of re-organisation.

#### Use randomization instead!

7.6 Skip Lists

#### Insert:

- A search operation gives you the insert position for element x in every list.
- ► Flip a coin until it shows head, and record the number t ∈ {1,2,...} of trials needed.
- lnsert x into lists  $L_0, \ldots, L_{t-1}$ .

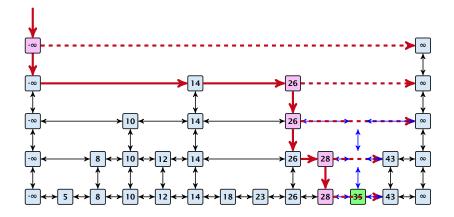

#### Delete:

- > You get all predecessors via backward pointers.
- Delete x in all lists it actually appears in.

# The time for both operations is dominated by the search time.

Insert (35):

7.6 Skip Lists

11. Apr. 2018 210/550

#### Definition 20 (High Probability)

We say a **randomized** algorithm has running time  $O(\log n)$  with high probability if for any constant  $\alpha$  the running time is at most  $O(\log n)$  with probability at least  $1 - \frac{1}{n^{\alpha}}$ .

Here the O-notation hides a constant that may depend on  $\alpha$ .

7.6 Skip Lists

## **High Probability**

Suppose there are polynomially many events  $E_1, E_2, ..., E_\ell$ ,  $\ell = n^c$  each holding with high probability (e.g.  $E_i$  may be the event that the *i*-th search in a skip list takes time at most  $O(\log n)$ ).

Then the probability that all  $E_i$  hold is at least

$$\Pr[E_1 \wedge \cdots \wedge E_{\ell}] = 1 - \Pr[\bar{E}_1 \vee \cdots \vee \bar{E}_{\ell}]$$
  
$$\geq 1 - n^c \cdot n^{-\alpha}$$
  
$$= 1 - n^{c-\alpha} .$$

This means  $\Pr[E_1 \land \cdots \land E_\ell]$  holds with high probability.

7.6 Skip Lists

11. Apr. 2018 212/550

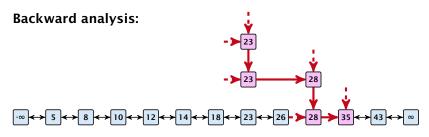

#### Lemma 21

A search (and, hence, also insert and delete) in a skip list with n elements takes time O(logn) with high probability (w. h. p.).

7.6 Skip Lists

11. Apr. 2018 213/550

At each point the path goes up with probability 1/2 and left with probability 1/2.

We show that w.h.p:

- A "long" search path must also go very high.
- There are no elements in high lists.

From this it follows that w.h.p. there are no long paths.

$$\left(\frac{n}{k}\right)^k \le \binom{n}{k} \le \left(\frac{en}{k}\right)^k$$

$$\binom{n}{k} = \frac{n!}{k! \cdot (n-k)!} = \frac{n \cdot \ldots \cdot (n-k+1)}{k \cdot \ldots \cdot 1} \ge \left(\frac{n}{k}\right)^k$$

$$\binom{n}{k} = \frac{n \cdot \ldots \cdot (n-k+1)}{k!} \le \frac{n^k}{k!} = \frac{n^k \cdot k^k}{k^k \cdot k!}$$
$$= \left(\frac{n}{k}\right)^k \cdot \frac{k^k}{k!} \le \left(\frac{en}{k}\right)^k$$

11. Apr. 2018 215/550 Let  $E_{z,k}$  denote the event that a search path is of length z (number of edges) but does not visit a list above  $L_k$ .

In particular, this means that during the construction in the backward analysis we see at most k heads (i.e., coin flips that tell you to go up) in z trials.

7.6 Skip Lists

 $\Pr[E_{z,k}] \leq \Pr[\text{at most } k \text{ heads in } z \text{ trials}]$ 

$$\leq \binom{z}{k} 2^{-(z-k)} \leq \left(\frac{ez}{k}\right)^k 2^{-(z-k)} \leq \left(\frac{2ez}{k}\right)^k 2^{-z}$$

choosing  $k = \gamma \log n$  with  $\gamma \ge 1$  and  $z = (\beta + \alpha)\gamma \log n$ 

$$\leq \left(\frac{2ez}{k}\right)^{k} 2^{-\beta k} \cdot n^{-\gamma \alpha} \leq \left(\frac{2ez}{2^{\beta}k}\right)^{k} \cdot n^{-\alpha}$$
$$\leq \left(\frac{2e(\beta + \alpha)}{2^{\beta}}\right)^{k} n^{-\alpha}$$

now choosing  $\beta = 6\alpha$  gives

$$\leq \left(\frac{42\alpha}{64^{\alpha}}\right)^k n^{-\alpha} \leq n^{-\alpha}$$

for  $\alpha \geq 1$ .

7.6 Skip Lists

11. Apr. 2018 217/550

So far we fixed  $k = \gamma \log n$ ,  $\gamma \ge 1$ , and  $z = 7\alpha \gamma \log n$ ,  $\alpha \ge 1$ .

This means that a search path of length  $\Omega(\log n)$  visits a list on a level  $\Omega(\log n)$ , w.h.p.

Let  $A_{k+1}$  denote the event that the list  $L_{k+1}$  is non-empty. Then

$$\Pr[A_{k+1}] \le n2^{-(k+1)} \le n^{-(\gamma-1)}$$

For the search to take at least  $z = 7\alpha \gamma \log n$  steps either the event  $E_{z,k}$  or the event  $A_{k+1}$  must hold. Hence,

 $\Pr[\text{search requires } z \text{ steps}] \le \Pr[E_{z,k}] + \Pr[A_{k+1}]$  $\le n^{-\alpha} + n^{-(\gamma-1)}$ 

This means, the search requires at most *z* steps, w. h. p.

# 7.7 Hashing

#### Dictionary:

- S. insert(x): Insert an element x.
- ► *S*. delete(*x*): Delete the element pointed to by *x*.
- S. search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

So far we have implemented the search for a key by carefully choosing split-elements.

Then the memory location of an object x with key k is determined by successively comparing k to split-elements.

Hashing tries to directly compute the memory location from the given key. The goal is to have constant search time.

# 7.7 Hashing

#### **Definitions:**

- Universe U of keys, e.g.,  $U \subseteq \mathbb{N}_0$ . U very large.
- Set  $S \subseteq U$  of keys,  $|S| = m \le |U|$ .
- Array  $T[0, \ldots, n-1]$  hash-table.
- Hash function  $h: U \rightarrow [0, \dots, n-1]$ .

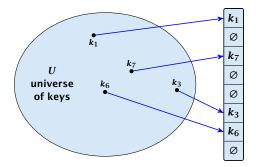

#### The hash-function *h* should fulfill:

- Fast to evaluate.
- Small storage requirement.
- Good distribution of elements over the whole table.

# **Direct Addressing**

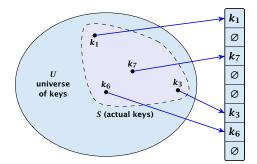

Ideally the hash function maps all keys to different memory locations.

This special case is known as Direct Addressing. It is usually very unrealistic as the universe of keys typically is quite large, and in particular larger than the available memory.

## **Perfect Hashing**

Suppose that we know the set S of actual keys (no insert/no delete). Then we may want to design a simple hash-function that maps all these keys to different memory locations.

Such a hash function *h* is called a perfect hash function for set *S*.

If we do not know the keys in advance, the best we can hope for is that the hash function distributes keys evenly across the table.

#### **Problem: Collisions**

Usually the universe U is much larger than the table-size n.

Hence, there may be two elements  $k_1, k_2$  from the set S that map to the same memory location (i.e.,  $h(k_1) = h(k_2)$ ). This is called a collision.

Typically, collisions do not appear once the size of the set *S* of actual keys gets close to *n*, but already when  $|S| \ge \omega(\sqrt{n})$ .

#### Lemma 22

The probability of having a collision when hashing m elements into a table of size n under uniform hashing is at least

$$1 - e^{-\frac{m(m-1)}{2n}} \approx 1 - e^{-\frac{m^2}{2n}}$$
.

#### **Uniform hashing**:

Choose a hash function uniformly at random from all functions  $f: U \rightarrow [0, ..., n-1]$ .

7.7 Hashing

11. Apr. 2018 224/550

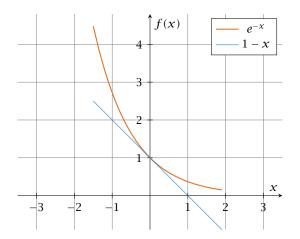

Proof.

Let  $A_{m,n}$  denote the event that inserting m keys into a table of size n does not generate a collision. Then

$$\Pr[A_{m,n}] = \prod_{\ell=1}^{m} \frac{n-\ell+1}{n} = \prod_{j=0}^{m-1} \left(1 - \frac{j}{n}\right)$$
$$\leq \prod_{j=0}^{m-1} e^{-j/n} = e^{-\sum_{j=0}^{m-1} \frac{j}{n}} = e^{-\frac{m(m-1)}{2n}}$$

Here the first equality follows since the  $\ell$ -th element that is hashed has a probability of  $\frac{n-\ell+1}{n}$  to not generate a collision under the condition that the previous elements did not induce collisions.

The inequality  $1 - x \le e^{-x}$  is derived by stopping the Taylor-expansion of  $e^{-x}$  after the second term.

Ernst Mayr, Harald Räcke

7.7 Hashing

11. Apr. 2018 226/550

# **Resolving Collisions**

The methods for dealing with collisions can be classified into the two main types

- open addressing, aka. closed hashing
- hashing with chaining, aka. closed addressing, open hashing.

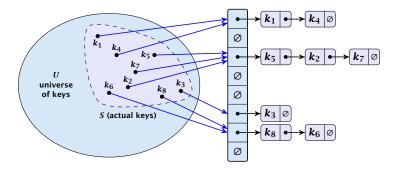

There are applications e.g. computer chess where you do not resolve collisions at all.

#### Hashing with Chaining

Arrange elements that map to the same position in a linear list.

- Access: compute h(x) and search list for key[x].
- Insert: insert at the front of the list.

7.7 Hashing

11. Apr. 2018 228/550

Let A denote a strategy for resolving collisions. We use the following notation:

- A<sup>+</sup> denotes the average time for a successful search when using A;
- A<sup>-</sup> denotes the average time for an unsuccessful search when using A;
- We parameterize the complexity results in terms of  $\alpha := \frac{m}{n}$ , the so-called fill factor of the hash-table.

We assume uniform hashing for the following analysis.

The time required for an unsuccessful search is 1 plus the length of the list that is examined. The average length of a list is  $\alpha = \frac{m}{n}$ . Hence, if A is the collision resolving strategy "Hashing with Chaining" we have

 $A^- = 1 + \alpha \ .$ 

For a successful search observe that we do **not** choose a list at random, but we consider a random key k in the hash-table and ask for the search-time for k.

This is 1 plus the number of elements that lie before k in k's list.

Let  $k_{\ell}$  denote the  $\ell$ -th key inserted into the table.

m

Let for two keys  $k_i$  and  $k_j$ ,  $X_{ij}$  denote the indicator variable for the event that  $k_i$  and  $k_j$  hash to the same position. Clearly,  $\Pr[X_{ij} = 1] = 1/n$  for uniform hashing.

The expected successful search cost is

keys before  $k_i$ 

$$\mathbb{E}\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right]$$
 cost for key k

200

7.7 Hashing

11. Apr. 2018 231/550

$$E\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right] = \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}E\left[X_{ij}\right]\right)$$

$$= \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}\frac{1}{n}\right)$$

$$= 1+\frac{1}{mn}\sum_{i=1}^{m}(m-i)$$

$$= 1+\frac{1}{mn}\left(m^{2}-\frac{m(m+1)}{2}\right)$$

$$= 1+\frac{m-1}{2n} = 1+\frac{\alpha}{2}-\frac{\alpha}{2m} .$$

Hence, the expected cost for a successful search is  $A^+ \leq 1 + \frac{\alpha}{2}$ .

החוחר	Ernst Mayr, Harald	
	Ernst Mayr, Harald	Räcke

### Disadvantages:

- pointers increase memory requirements
- pointers may lead to bad cache efficiency

#### Advantages:

- no à priori limit on the number of elements
- deletion can be implemented efficiently
- by using balanced trees instead of linked list one can also obtain worst-case guarantees.

# **Open Addressing**

All objects are stored in the table itself.

Define a function h(k, j) that determines the table-position to be examined in the *j*-th step. The values  $h(k, 0), \ldots, h(k, n-1)$  must form a permutation of  $0, \ldots, n-1$ .

**Search**(*k*): Try position h(k, 0); if it is empty your search fails; otw. continue with h(k, 1), h(k, 2), ....

**Insert**(x): Search until you find an empty slot; insert your element there. If your search reaches h(k, n - 1), and this slot is non-empty then your table is full.

# **Open Addressing**

Choices for h(k, j):

- Linear probing:
   h(k, i) = h(k) + i mod n
   (sometimes: h(k, i) = h(k) + ci mod n).
- Quadratic probing:  $h(k,i) = h(k) + c_1i + c_2i^2 \mod n.$

### • Double hashing: $h(k, i) = h_1(k) + ih_2(k) \mod n.$

For quadratic probing and double hashing one has to ensure that the search covers all positions in the table (i.e., for double hashing  $h_2(k)$  must be relatively prime to n (teilerfremd); for quadratic probing  $c_1$  and  $c_2$  have to be chosen carefully).

# **Linear Probing**

- Advantage: Cache-efficiency. The new probe position is very likely to be in the cache.
- Disadvantage: Primary clustering. Long sequences of occupied table-positions get longer as they have a larger probability to be hit. Furthermore, they can merge forming larger sequences.

#### Lemma 23

Let *L* be the method of linear probing for resolving collisions:

$$L^{+} \approx \frac{1}{2} \left( 1 + \frac{1}{1 - \alpha} \right)$$
$$L^{-} \approx \frac{1}{2} \left( 1 + \frac{1}{(1 - \alpha)^{2}} \right)$$

7.7 Hashing

11. Apr. 2018 236/550

### **Quadratic Probing**

- Not as cache-efficient as Linear Probing.
- Secondary clustering: caused by the fact that all keys mapped to the same position have the same probe sequence.

#### Lemma 24

Let Q be the method of quadratic probing for resolving collisions:

$$Q^{+} \approx 1 + \ln\left(\frac{1}{1-\alpha}\right) - \frac{\alpha}{2}$$
$$Q^{-} \approx \frac{1}{1-\alpha} + \ln\left(\frac{1}{1-\alpha}\right) - \alpha$$

7.7 Hashing

11. Apr. 2018 237/550

### **Double Hashing**

Any probe into the hash-table usually creates a cache-miss.

#### Lemma 25

Let A be the method of double hashing for resolving collisions:

$$D^+ \approx \frac{1}{\alpha} \ln\left(\frac{1}{1-\alpha}\right)$$
  
 $D^- \approx \frac{1}{1-\alpha}$ 

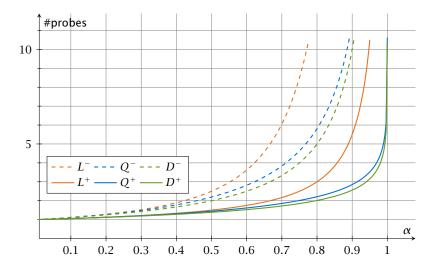

### **Open Addressing**

#### Some values:

# **Open Addressing**

7.7 Hashing

11. Apr. 2018 240/550

We analyze the time for a search in a very idealized Open Addressing scheme.

► The probe sequence h(k, 0), h(k, 1), h(k, 2),... is equally likely to be any permutation of (0, 1,..., n − 1).

Let X denote a random variable describing the number of probes in an unsuccessful search.

Let  $A_i$  denote the event that the *i*-th probe occurs and is to a non-empty slot.

 $\Pr[A_1 \cap A_2 \cap \dots \cap A_{i-1}]$ =  $\Pr[A_1] \cdot \Pr[A_2 \mid A_1] \cdot \Pr[A_3 \mid A_1 \cap A_2] \cdot \dots \cdot \Pr[A_{i-1} \mid A_1 \cap \dots \cap A_{i-2}]$ 

$$\Pr[X \ge i] = \frac{m}{n} \cdot \frac{m-1}{n-1} \cdot \frac{m-2}{n-2} \cdot \dots \cdot \frac{m-i+2}{n-i+2}$$
$$\le \left(\frac{m}{n}\right)^{i-1} = \alpha^{i-1} \ .$$

7.7 Hashing

11. Apr. 2018 242/550

$$\mathbb{E}[X] = \sum_{i=1}^{\infty} \Pr[X \ge i] \le \sum_{i=1}^{\infty} \alpha^{i-1} = \sum_{i=0}^{\infty} \alpha^{i} = \frac{1}{1-\alpha} .$$

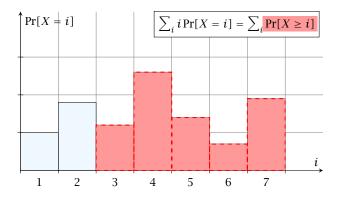

$$\frac{1}{1-\alpha} = 1 + \alpha + \alpha^2 + \alpha^3 + \dots$$

7.7 Hashing

11. Apr. 2018 243/550

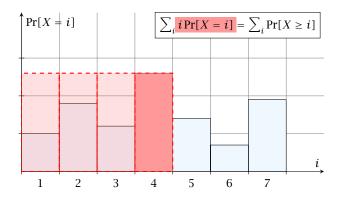

i = 3

The *j*-th rectangle appears in both sums *j* times. (*j* times in the first due to multiplication with *j*; and *j* times in the second for summands i = 1, 2, ..., j)

Ernst Mayr, Harald Räcke

i = 4

The *j*-th rectangle appears in both sums *j* times. (*j* times in the first due to multiplication with *j*; and *j* times in the second for summands i = 1, 2, ..., j)

The number of probes in a successful search for k is equal to the number of probes made in an unsuccessful search for k at the time that k is inserted.

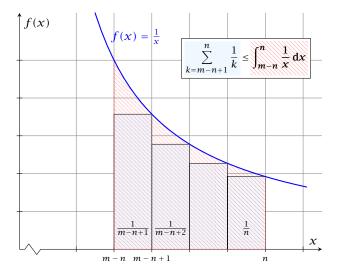

Let k be the i + 1-st element. The expected time for a search for k is at most  $\frac{1}{1-i/n} = \frac{n}{n-i}$ .

$$\frac{1}{m} \sum_{i=0}^{m-1} \frac{n}{n-i} = \frac{n}{m} \sum_{i=0}^{m-1} \frac{1}{n-i} = \frac{1}{\alpha} \sum_{k=n-m+1}^{n} \frac{1}{k}$$
$$\leq \frac{1}{\alpha} \int_{n-m}^{n} \frac{1}{x} dx = \frac{1}{\alpha} \ln \frac{n}{n-m} = \frac{1}{\alpha} \ln \frac{1}{1-\alpha} .$$

7.7 Hashing

11. Apr. 2018 246/550

### **Deletions in Hashtables**

#### How do we delete in a hash-table?

- For hashing with chaining this is not a problem. Simply search for the key, and delete the item in the corresponding list.
- For open addressing this is difficult.

### **Deletions in Hashtables**

- Simply removing a key might interrupt the probe sequence of other keys which then cannot be found anymore.
- One can delete an element by replacing it with a deleted-marker.
  - During an insertion if a deleted-marker is encountered an element can be inserted there.
  - During a search a deleted-marker must not be used to terminate the probe sequence.
- The table could fill up with deleted-markers leading to bad performance.
- If a table contains many deleted-markers (linear fraction of the keys) one can rehash the whole table and amortize the cost for this rehash against the cost for the deletions.

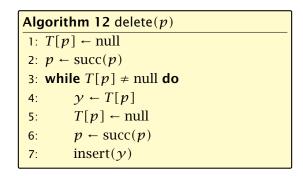

# **Deletions for Linear Probing**

- For Linear Probing one can delete elements without using deletion-markers.
- Upon a deletion elements that are further down in the probe-sequence may be moved to guarantee that they are still found during a search.

# **Deletions for Linear Probing**

 $\ensuremath{\textit{p}}$  is the index into the table-cell that contains the object to be deleted.

Pointers into the hash-table become invalid.

Regardless, of the choice of hash-function there is always an input (a set of keys) that has a very poor worst-case behaviour.

Therefore, so far we assumed that the hash-function is random so that regardless of the input the average case behaviour is good.

However, the assumption of uniform hashing that h is chosen randomly from all functions  $f: U \rightarrow [0, ..., n-1]$  is clearly unrealistic as there are  $n^{|U|}$  such functions. Even writing down such a function would take  $|U| \log n$  bits.

Universal hashing tries to define a set  $\mathcal{H}$  of functions that is much smaller but still leads to good average case behaviour when selecting a hash-function uniformly at random from  $\mathcal{H}$ .

#### **Definition 26**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called universal if for all  $u_1, u_2 \in U$  with  $u_1 \neq u_2$ 

$$\Pr[h(u_1) = h(u_2)] \le \frac{1}{n}$$
,

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

Note that this means that the probability of a collision between two arbitrary elements is at most  $\frac{1}{n}$ .

### **Definition 27**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called 2-independent (pairwise independent) if the following two conditions hold

- For any key  $u \in U$ , and  $t \in \{0, ..., n-1\} \Pr[h(u) = t] = \frac{1}{n}$ , i.e., a key is distributed uniformly within the hash-table.
- For all u<sub>1</sub>, u<sub>2</sub> ∈ U with u<sub>1</sub> ≠ u<sub>2</sub>, and for any two hash-positions t<sub>1</sub>, t<sub>2</sub>:

$$\Pr[h(u_1) = t_1 \wedge h(u_2) = t_2] \le \frac{1}{n^2} .$$

### This requirement clearly implies a universal hash-function.

#### **Definition 28**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called *k*-independent if for any choice of  $\ell \leq k$  distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

$$\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_\ell) = t_\ell] \leq \frac{1}{n^\ell} ,$$

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

#### **Definition 29**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called  $(\mu, k)$ -independent if for any choice of  $\ell \leq k$  distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

$$\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_\ell) = t_\ell] \leq \frac{\mu}{n^\ell} ,$$

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

Let  $U := \{0, ..., p - 1\}$  for a prime p. Let  $\mathbb{Z}_p := \{0, ..., p - 1\}$ , and let  $\mathbb{Z}_p^* := \{1, ..., p - 1\}$  denote the set of invertible elements in  $\mathbb{Z}_p$ .

Define

 $h_{a,b}(x) := (ax + b \mod p) \mod n$ 

#### Lemma 30

The class

$$\mathcal{H} = \{h_{a,b} \mid a \in \mathbb{Z}_p^*, b \in \mathbb{Z}_p\}$$

is a universal class of hash-functions from U to  $\{0, ..., n-1\}$ .

7.7 Hashing

11. Apr. 2018 256/550

### Proof.

Let  $x, y \in U$  be two distinct keys. We have to show that the probability of a collision is only 1/n.

 $\bullet ax + b \not\equiv ay + b \pmod{p}$ 

If  $x \neq y$  then  $(x - y) \not\equiv 0 \pmod{p}$ .

Multiplying with  $a \not\equiv 0 \pmod{p}$  gives

 $a(x-y) \not\equiv 0 \pmod{p}$ 

where we use that  $\mathbb{Z}_p$  is a field (Körper) and, hence, has no zero divisors (nullteilerfrei).

The hash-function does not generate collisions before the (mod n)-operation. Furthermore, every choice (a, b) is mapped to a different pair (t<sub>x</sub>, t<sub>y</sub>) with t<sub>x</sub> := ax + b and t<sub>y</sub> := ay + b.

This holds because we can compute *a* and *b* when given  $t_x$  and  $t_y$ :

- $t_{x} \equiv ax + b \qquad (\text{mod } p)$  $t_{y} \equiv ay + b \qquad (\text{mod } p)$
- $t_{x} t_{y} \equiv a(x y) \qquad (\text{mod } p)$  $t_{y} \equiv ay + b \qquad (\text{mod } p)$ 
  - $a \equiv (t_x t_y)(x y)^{-1} \pmod{p}$  $b \equiv t_y - ay \pmod{p}$

There is a one-to-one correspondence between hash-functions (pairs (a, b),  $a \neq 0$ ) and pairs  $(t_x, t_y)$ ,  $t_x \neq t_y$ .

Therefore, we can view the first step (before the mod *n*-operation) as choosing a pair  $(t_x, t_y)$ ,  $t_x \neq t_y$  uniformly at random.

What happens when we do the mod n operation?

Fix a value  $t_x$ . There are p - 1 possible values for choosing  $t_y$ .

From the range 0, ..., p - 1 the values  $t_x, t_x + n, t_x + 2n, ...$  map to  $t_x$  after the modulo-operation. These are at most  $\lceil p/n \rceil$  values.

As  $t_y \neq t_x$  there are

$$\left\lceil \frac{p}{n} \right\rceil - 1 \le \frac{p}{n} + \frac{n-1}{n} - 1 \le \frac{p-1}{n}$$

possibilities for choosing  $t_{\mathcal{Y}}$  such that the final hash-value creates a collision.

This happens with probability at most  $\frac{1}{n}$ .

It is also possible to show that  $\mathcal H$  is an (almost) pairwise independent class of hash-functions.

$$\frac{\left\lfloor \frac{p}{n} \right\rfloor^2}{p(p-1)} \le \Pr_{t_x \neq t_y \in \mathbb{Z}_p^2} \left[ \begin{array}{c} t_x \mod n = h_1 \\ t_y \mod n = h_2 \end{array} \right] \le \frac{\left\lceil \frac{p}{n} \right\rceil^2}{p(p-1)}$$

Note that the middle is the probability that  $h(x) = h_1$  and  $h(y) = h_2$ . The total number of choices for  $(t_x, t_y)$  is p(p-1). The number of choices for  $t_x$   $(t_y)$  such that  $t_x \mod n = h_1$  $(t_y \mod n = h_2)$  lies between  $\lfloor \frac{p}{n} \rfloor$  and  $\lceil \frac{p}{n} \rceil$ .

**Definition 31** Let  $d \in \mathbb{N}$ ;  $q \ge (d+1)n$  be a prime; and let  $\tilde{a} \in \{0, \dots, q-1\}^{d+1}$ . Define for  $x \in \{0, \dots, q-1\}$ 

$$h_{\bar{a}}(x) := \left(\sum_{i=0}^{d} a_i x^i \mod q\right) \mod n \; .$$

Let  $\mathcal{H}_n^d := \{h_{\bar{a}} \mid \bar{a} \in \{0, \dots, q-1\}^{d+1}\}$ . The class  $\mathcal{H}_n^d$  is (e, d+1)-independent.

Note that in the previous case we had d = 1 and chose  $a_d \neq 0$ .

For the coefficients  $\bar{a} \in \{0, \dots, q-1\}^{d+1}$  let  $f_{\bar{a}}$  denote the polynomial

$$f_{\bar{a}}(x) = \left(\sum_{i=0}^{d} a_i x^i\right) \mod q$$

The polynomial is defined by d + 1 distinct points.

7.7 Hashing

11. Apr. 2018 263/550

#### **Universal Hashing**

Fix  $\ell \leq d + 1$ ; let  $x_1, \ldots, x_\ell \in \{0, \ldots, q - 1\}$  be keys, and let  $t_1, \ldots, t_\ell$  denote the corresponding hash-function values.

Let  $A^{\ell} = \{h_{\tilde{a}} \in \mathcal{H} \mid h_{\tilde{a}}(x_i) = t_i \text{ for all } i \in \{1, \dots, \ell\}\}$ Then

$$h_{\tilde{a}} \in A^{\ell} \Leftrightarrow h_{\tilde{a}} = f_{\tilde{a}} \bmod n$$
 and

$$f_{\bar{a}}(x_i) \in \underbrace{\{t_i + \alpha \cdot n \mid \alpha \in \{0, \dots, \lceil \frac{q}{n} \rceil - 1\}\}}_{=:B_i}$$

In order to obtain the cardinality of  $A^{\ell}$  we choose our polynomial by fixing d + 1 points.

We first fix the values for inputs  $x_1, \ldots, x_\ell$ . We have

$$|B_1| \cdot \ldots \cdot |B_\ell|$$

possibilities to do this (so that  $h_{\tilde{a}}(x_i) = t_i$ ).

•  $A^{\ell}$  denotes the set of hashfunctions such that every  $x_i$ hits its pre-defined position  $t_i$ .

 B<sub>i</sub> is the set of positions that f<sub>ā</sub> can hit so that h<sub>ā</sub> still hits t<sub>i</sub>.

## **Universal Hashing**

Now, we choose  $d - \ell + 1$  other inputs and choose their value arbitrarily. We have  $q^{d-\ell+1}$  possibilities to do this.

Therefore we have

$$|B_1| \cdot \ldots \cdot |B_\ell| \cdot q^{d-\ell+1} \leq \lceil \frac{q}{n} \rceil^\ell \cdot q^{d-\ell+1}$$

possibilities to choose  $\bar{a}$  such that  $h_{\bar{a}} \in A_{\ell}$ .

## **Universal Hashing**

Therefore the probability of choosing  $h_{\tilde{a}}$  from  $A_{\ell}$  is only

$$\begin{aligned} \frac{\lceil \frac{q}{n} \rceil^{\ell} \cdot q^{d-\ell+1}}{q^{d+1}} &\leq \frac{(\frac{q+n}{n})^{\ell}}{q^{\ell}} \leq \left(\frac{q+n}{q}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \\ &\leq \left(1 + \frac{1}{\ell}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \leq \frac{e}{n^{\ell}} \end{aligned}$$

This shows that the  $\mathcal{H}$  is (e, d + 1)-universal.

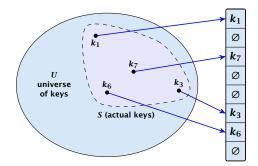

The last step followed from  $q \ge (d+1)n$ , and  $\ell \le d+1$ .

7.7 Hashing

11. Apr. 2018 266/550

Suppose that we **know** the set S of actual keys (no insert/no delete). Then we may want to design a **simple** hash-function that maps all these keys to different memory locations.

7.7 Hashing

11. Apr. 2018 267/550

Let m = |S|. We could simply choose the hash-table size very large so that we don't get any collisions.

Using a universal hash-function the expected number of collisions is

$$\mathbb{E}[\texttt{\#Collisions}] = \binom{m}{2} \cdot \frac{1}{n} .$$

If we choose  $n = m^2$  the expected number of collisions is strictly less than  $\frac{1}{2}$ .

Can we get an upper bound on the probability of having collisions?

The probability of having 1 or more collisions can be at most  $\frac{1}{2}$  as otherwise the expectation would be larger than  $\frac{1}{2}$ .

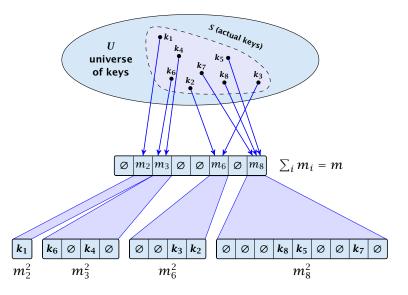

We can find such a hash-function by a few trials.

However, a hash-table size of  $n = m^2$  is very very high.

We construct a two-level scheme. We first use a hash-function that maps elements from S to m buckets.

Let  $m_j$  denote the number of items that are hashed to the *j*-th bucket. For each bucket we choose a second hash-function that maps the elements of the bucket into a table of size  $m_j^2$ . The second function can be chosen such that all elements are mapped to different locations.

7.7 Hashing

11. Apr. 2018 270/550

The total memory that is required by all hash-tables is  $\mathcal{O}(\sum_{i} m_{i}^{2})$ . Note that  $m_{j}$  is a random variable.

$$E\left[\sum_{j} m_{j}^{2}\right] = E\left[2\sum_{j} \binom{m_{j}}{2} + \sum_{j} m_{j}\right]$$
$$= 2E\left[\sum_{j} \binom{m_{j}}{2}\right] + E\left[\sum_{j} m_{j}\right]$$

The first expectation is simply the expected number of collisions, for the first level. Since we use universal hashing we have

$$= 2\binom{m}{2}\frac{1}{m} + m = 2m - 1 \quad .$$

7.7 Hashing

11. Apr. 2018 271/550

We need only  $\mathcal{O}(m)$  time to construct a hash-function h with  $\sum_j m_j^2 = \mathcal{O}(4m)$ , because with probability at least 1/2 a random function from a universal family will have this property.

Then we construct a hash-table  $h_j$  for every bucket. This takes expected time  $\mathcal{O}(m_j)$  for every bucket. A random function  $h_j$  is collision-free with probability at least 1/2. We need  $\mathcal{O}(m_j)$  to test this.

We only need that the hash-functions are chosen from a universal family!!!

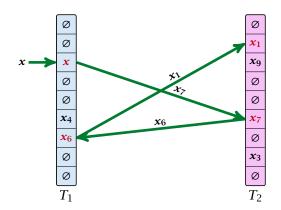

#### Goal:

Try to generate a hash-table with constant worst-case search time in a dynamic scenario.

- ▶ Two hash-tables  $T_1[0, ..., n-1]$  and  $T_2[0, ..., n-1]$ , with hash-functions  $h_1$ , and  $h_2$ .
- An object x is either stored at location  $T_1[h_1(x)]$  or  $T_2[h_2(x)]$ .
- A search clearly takes constant time if the above constraint is met.

Insert:

7.7 Hashing

11. Apr. 2018 274/550

#### Algorithm 13 Cuckoo-Insert(*x*)

```
1: if T_1[h_1(x)] = x \vee T_2[h_2(x)] = x then return
```

```
2: steps ← 1
```

```
3: while steps \leq maxsteps do
```

```
4: exchange x and T_1[h_1(x)]
```

```
5: if x = null then return
```

```
6: exchange x and T_2[h_2(x)]
```

```
7: if x = null then return
```

```
8: steps \leftarrow steps +1
```

```
9: rehash() // change hash-functions; rehash everything
```

```
10: Cuckoo-Insert(x)
```

- We call one iteration through the while-loop a step of the algorithm.
- We call a sequence of iterations through the while-loop without the termination condition becoming true a phase of the algorithm.
- We say a phase is successful if it is not terminated by the maxstep-condition, but the while loop is left because x = null.

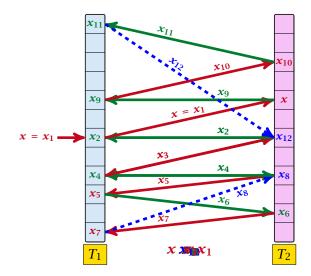

#### What is the expected time for an insert-operation?

We first analyze the probability that we end-up in an infinite loop (that is then terminated after maxsteps steps).

Formally what is the probability to enter an infinite loop that touches *s* different keys?

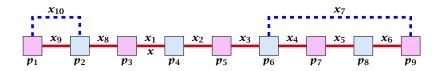

#### **Cuckoo Hashing: Insert**

7.7 Hashing

11. Apr. 2018 278/550

A cycle-structure of size *s* is defined by

- ▶ s 1 different cells (alternating btw. cells from  $T_1$  and  $T_2$ ).
- ► *s* distinct keys  $x = x_1, x_2, ..., x_s$ , linking the cells.
- The leftmost cell is "linked forward" to some cell on the right.
- The rightmost cell is "linked backward" to a cell on the left.
- One link represents key *x*; this is where the counting starts.

A cycle-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$  from  $T_1$  and a cell  $p_j$  from  $T_2$ ) we have

$$h_1(x_\ell) = p_i$$
 and  $h_2(x_\ell) = p_j$ 

#### **Observation:**

If during a phase the insert-procedure runs into a cycle there must exist an active cycle structure of size  $s \ge 3$ .

What is the probability that all keys in a cycle-structure of size s correctly map into their  $T_1$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_1$  is a  $(\mu, s)$ -independent hash-function.

What is the probability that all keys in the cycle-structure of size s correctly map into their  $T_2$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_2$  is a  $(\mu, s)$ -independent hash-function.

These events are independent.

The probability that a given cycle-structure of size *s* is active is at most  $\frac{\mu^2}{n^{2s}}$ .

What is the probability that there exists an active cycle structure of size *s*?

The number of cycle-structures of size *s* is at most

 $s^3 \cdot n^{s-1} \cdot m^{s-1}$  .

- There are at most s<sup>2</sup> possibilities where to attach the forward and backward links.
- There are at most s possibilities to choose where to place key x.
- There are m<sup>s-1</sup> possibilities to choose the keys apart from x.
- There are  $n^{s-1}$  possibilities to choose the cells.

The probability that there exists an active cycle-structure is therefore at most

$$\begin{split} \sum_{s=3}^{\infty} s^3 \cdot n^{s-1} \cdot m^{s-1} \cdot \frac{\mu^2}{n^{2s}} &= \frac{\mu^2}{nm} \sum_{s=3}^{\infty} s^3 \left(\frac{m}{n}\right)^s \\ &\leq \frac{\mu^2}{m^2} \sum_{s=3}^{\infty} s^3 \left(\frac{1}{1+\epsilon}\right)^s \leq \mathcal{O}\left(\frac{1}{m^2}\right) \end{split}$$

Here we used the fact that  $(1 + \epsilon)m \le n$ .

Hence,

$$\Pr[\mathsf{cycle}] = \mathcal{O}\left(\frac{1}{m^2}\right)$$
.

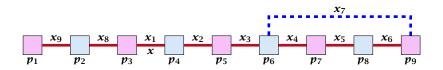

7.7 Hashing

11. Apr. 2018 284/550

Now, we analyze the probability that a phase is not successful without running into a closed cycle.

Sequence of visited keys:

 $x = x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_3, x_2, x_1 = x, x_8, x_9, \dots$ 

7.7 Hashing

11. Apr. 2018 286/550 Consider the sequence of not necessarily distinct keys starting with x in the order that they are visited during the phase.

**Lemma 32** If the sequence is of length p then there exists a sub-sequence of at least  $\frac{p+2}{3}$  keys starting with x of distinct keys.

#### Proof.

Taking  $x_1 \rightarrow \cdots \rightarrow x_i$  twice, and  $x_1 \rightarrow x_{i+1} \rightarrow \dots x_j$  once gives  $2i + (j - i + 1) = i + j + 1 \ge p + 2$  keys. Hence, one of the sequences contains at least (p + 2)/3 keys.

Let *i* be the number of keys (including x) that we see before the first repeated key. Let *j* denote the total number of distinct keys.

The sequence is of the form:

 $x = x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i \rightarrow x_r \rightarrow x_{r-1} \rightarrow \cdots \rightarrow x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$ 

As  $r \leq i - 1$  the length p of the sequence is

 $p=i+r+(j-i)\leq i+j-1 \ .$ 

Either sub-sequence  $x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i$  or sub-sequence  $x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$  has at least  $\frac{p+2}{3}$  elements.

A path-structure of size s is defined by

- ▶ s + 1 different cells (alternating btw. cells from  $T_1$  and  $T_2$ ).
- ▶ *s* distinct keys  $x = x_1, x_2, ..., x_s$ , linking the cells.
- The leftmost cell is either from  $T_1$  or  $T_2$ .

A path-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$  from  $T_1$  and a cell  $p_j$  from  $T_2$ ) we have

$$h_1(x_{\ell}) = p_i$$
 and  $h_2(x_{\ell}) = p_j$ 

#### **Observation:**

If a phase takes at least t steps without running into a cycle there must exist an active path-structure of size (2t + 2)/3.

```
Note that we count complete steps. A search that touches 2t or 2t + 1 keys takes t steps.
```

Ernst Mayr, Harald Räcke

7.7 Hashing

11. Apr. 2018 290/550

The probability that a given path-structure of size *s* is active is at most  $\frac{\mu^2}{n^{2s}}$ .

The probability that there exists an active path-structure of size s is at most

$$2 \cdot n^{s+1} \cdot m^{s-1} \cdot \frac{\mu^2}{n^{2s}}$$
$$\leq 2\mu^2 \left(\frac{m}{n}\right)^{s-1} \leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{s-1}$$

Plugging in s = (2t + 2)/3 gives

$$\leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t+2)/3-1} = 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3} \ .$$

7.7 Hashing

11. Apr. 2018 291/550

We choose  $maxsteps \ge 3\ell/2 + 1/2$ . Then the probability that a phase terminates unsuccessfully without running into a cycle is at most

Pr[unsuccessful | no cycle]  $\leq \Pr[\exists active path-structure of size at least \frac{2maxsteps+2}{2}]$  $\leq \Pr[\exists active path-structure of size at least <math>\ell + 1]$  $\leq \Pr[\exists active path-structure of size exactly \ell + 1]$  $\leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^\ell \leq \frac{1}{m^2}$ by choosing  $\ell \geq \log\left(\frac{1}{2\mu^2m^2}\right)/\log\left(\frac{1}{1+\epsilon}\right) = \log\left(2\mu^2m^2\right)/\log\left(1+\epsilon\right)$ This gives maxsteps =  $\Theta(\log m)$ . Note that the existence of a path structure of size larger than *s* implies the existence of a path structure of size exactly s.

So far we estimated

$$\Pr[\mathsf{cycle}] \le \mathcal{O}\Big(\frac{1}{m^2}\Big)$$

and

$$\Pr[\mathsf{unsuccessful} \mid \mathsf{no cycle}] \le \mathcal{O}\Big(\frac{1}{m^2}\Big)$$

#### Observe that

 $\begin{aligned} \Pr[\mathsf{successful}] &= \Pr[\mathsf{no cycle}] - \Pr[\mathsf{unsuccessful} \mid \mathsf{no cycle}] \\ &\geq c \cdot \Pr[\mathsf{no cycle}] \end{aligned}$ 

for a suitable constant c > 0.

This is a very weak (and trivial) statement but still sufficient for our asymptotic analysis.

The expected number of complete steps in the successful phase of an insert operation is:

E[number of steps | phase successful]

 $= \sum_{t \ge 1} \Pr[\text{search takes at least } t \text{ steps } | \text{ phase successful}]$ 

We have

Pr[search at least t steps | successful]

 $= \Pr[\text{search at least } t \text{ steps } \land \text{successful}] / \Pr[\text{successful}]$   $\leq \frac{1}{c} \Pr[\text{search at least } t \text{ steps } \land \text{successful}] / \Pr[\text{no cycle}]$   $\leq \frac{1}{c} \Pr[\text{search at least } t \text{ steps } \land \text{ no cycle}] / \Pr[\text{no cycle}]$   $= \frac{1}{c} \Pr[\text{search at least } t \text{ steps } | \text{ no cycle}] .$ 

Hence,

E[number of steps | phase successful]

$$\leq \frac{1}{c} \sum_{t \geq 1} \Pr[\text{search at least } t \text{ steps } | \text{ no cycle}]$$
  
$$\leq \frac{1}{c} \sum_{t \geq 1} 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3} = \frac{1}{c} \sum_{t \geq 0} 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2(t+1)-1)/3}$$
  
$$= \frac{2\mu^2}{c(1+\epsilon)^{1/3}} \sum_{t \geq 0} \left(\frac{1}{(1+\epsilon)^{2/3}}\right)^t = \mathcal{O}(1) \ .$$

This means the expected cost for a successful phase is constant (even after accounting for the cost of the incomplete step that finishes the phase).

A phase that is not successful induces cost for doing a complete rehash (this dominates the cost for the steps in the phase).

The probability that a phase is not successful is  $q = O(1/m^2)$ (probability  $O(1/m^2)$  of running into a cycle and probability  $O(1/m^2)$  of reaching massteps without running into a cycle).

A rehash try requires m insertions and takes expected constant time per insertion. It fails with probability p := O(1/m).

The expected number of unsuccessful rehashes is  $\sum_{i\geq 1} p^i = \frac{1}{1-p} - 1 = \frac{p}{1-p} = \mathcal{O}(p).$ 

Therefore the expected cost for re-hashes is  $\mathcal{O}(m) \cdot \mathcal{O}(p) = \mathcal{O}(1)$ .

#### **Formal Proof**

Let  $Y_i$  denote the event that the *i*-th rehash does not lead to a valid configuration (assuming *i*-th rehash occurs) (i.e., one of the m + 1 insertions fails):

 $\Pr[Y_i] \le (m+1) \cdot \mathcal{O}(1/m^2) \le \mathcal{O}(1/m) =: p .$ 

Let  $Z_i$  denote the event that the *i*-th rehash occurs: The 0-th (re)hash is the initial configuration when doing the insert. Insert. Pr[ $Z_i$ ]  $\leq \Pr[\wedge_{j=0}^{i-1}Y_j] \leq p^i$ 

Let  $X_i^s$ ,  $s \in \{1, ..., m + 1\}$  denote the cost for inserting the *s*-th element during the *i*-th rehash (assuming *i*-th rehash occurs):

$$\begin{split} \mathbf{E}[X_i^{S}] &= \mathbf{E}[\mathsf{steps} \mid \mathsf{phase \ successful}] \cdot \Pr[\mathsf{phase \ successful}] \\ &+ \max \mathsf{steps} \cdot \Pr[\mathsf{not \ successful}] = \mathcal{O}(1) \enspace . \end{split}$$

The expected cost for all rehashes is

 $\mathbf{E}\left[\sum_{i}\sum_{s}Z_{i}X_{i}^{s}\right]$ 

Note that  $Z_i$  is independent of  $X_j^s$ ,  $j \ge i$  (however, it is not independent of  $X_j^s$ , j < i). Hence,

$$E\left[\sum_{i}\sum_{s}Z_{i}X_{s}^{i}\right] = \sum_{i}\sum_{s}E[Z_{i}] \cdot E[X_{s}^{i}]$$
  
$$\leq \mathcal{O}(m) \cdot \sum_{i}p^{i}$$
  
$$\leq \mathcal{O}(m) \cdot \frac{p}{1-p}$$
  
$$= \mathcal{O}(1) .$$

#### What kind of hash-functions do we need?

Since maxsteps is  $\Theta(\log m)$  the largest size of a path-structure or cycle-structure contains just  $\Theta(\log m)$  different keys.

Therefore, it is sufficient to have  $(\mu, \Theta(\log m))$ -independent hash-functions.

## **Cuckoo Hashing**

#### How do we make sure that $n \ge (1 + \epsilon)m$ ?

- Let  $\alpha := 1/(1 + \epsilon)$ .
- Keep track of the number of elements in the table. When  $m \ge \alpha n$  we double n and do a complete re-hash (table-expand).
- Whenever *m* drops below  $\alpha n/4$  we divide *n* by 2 and do a rehash (table-shrink).
- Note that right after a change in table-size we have  $m = \alpha n/2$ . In order for a table-expand to occur at least  $\alpha n/2$  insertions are required. Similar, for a table-shrink at least  $\alpha n/4$  deletions must occur.
- Therefore we can amortize the rehash cost after a change in table-size against the cost for insertions and deletions.

## **Cuckoo Hashing**

#### Lemma 33

*Cuckoo Hashing has an expected constant insert-time and a worst-case constant search-time.* 

Note that the above lemma only holds if the fill-factor (number of keys/total number of hash-table slots) is at most  $\frac{1}{2(1+\epsilon)}$ .

The  $1/(2(1 + \epsilon))$  fill-factor comes from the fact that the total hash-table is of size 2n (because we have two tables of size n); moreover  $m \le (1 + \epsilon)n$ .

## Hashing

#### Bibliography

- [MS08] Kurt Mehlhorn, Peter Sanders: Algorithms and Data Structures — The Basic Toolbox, Springer, 2008
- [CLRS90] Thomas H. Cormen, Charles E. Leiserson, Ron L. Rivest, Clifford Stein: Introduction to algorithms (3rd ed.), MIT Press and McGraw-Hill, 2009

Chapter 4 of [MS08] contains a detailed description about Hashing with Linear Probing and Hashing with Chaining. Also the Perfect Hashing scheme can be found there.

The analysis of Hashing with Chaining under the assumption of uniform hashing can be found in Chapter 11.2 of [CLRS90]. Chapter 11.3.3 describes Universal Hashing. Collision resolution with Open Addressing is described in Chapter 11.4. Chapter 11.5 describes the Perfect Hashing scheme.

## **8 Priority Queues**

A Priority Queue *S* is a dynamic set data structure that supports the following operations:

- S. build(x<sub>1</sub>,..., x<sub>n</sub>): Creates a data-structure that contains just the elements x<sub>1</sub>,..., x<sub>n</sub>.
- S. insert(x): Adds element x to the data-structure.
- element *S*. minimum(): Returns an element  $x \in S$  with minimum key-value key[x].
- element S. delete-min(): Deletes the element with minimum key-value from S and returns it.
- boolean S. is-empty(): Returns true if the data-structure is empty and false otherwise.

Sometimes we also have

• S. merge(S'):  $S := S \cup S'$ ;  $S' := \emptyset$ .

## **8 Priority Queues**

An addressable Priority Queue also supports:

- handle S. insert(x): Adds element x to the data-structure, and returns a handle to the object for future reference.
- **S. delete(***h***):** Deletes element specified through handle *h*.
- S. decrease-key(h, k): Decreases the key of the element specified by handle h to k. Assumes that the key is at least k before the operation.

8 Priority Queues

## Dijkstra's Shortest Path Algorithm

```
Algorithm 14 Shortest-Path(G = (V, E, d), s \in V)
 1: Input: weighted graph G = (V, E, d); start vertex s;
 2: Output: key-field of every node contains distance from s;
 3: S.build(); // build empty priority queue
4: for all v \in V \setminus \{s\} do
5:
    v, kev \leftarrow \infty:
6: h_v \leftarrow S.insert(v);
7: s.key \leftarrow 0; S.insert(s);
8: while S.is-empty() = false do
      v \leftarrow S.delete-min():
9:
10: for all x \in V s.t. (v, x) \in E do
11:
               if x.key > v.key + d(v, x) then
                    S.decrease-key(h_x, v. key + d(v, x));
12:
13:
                    x.key \leftarrow v.key + d(v, x):
```

8 Priority Queues

## Prim's Minimum Spanning Tree Algorithm

```
Algorithm 15 Prim-MST(G = (V, E, d), s \in V)
 1: Input: weighted graph G = (V, E, d); start vertex s;
 2: Output: pred-fields encode MST;
 3: S.build(); // build empty priority queue
 4: for all v \in V \setminus \{s\} do
 5:
    v \cdot \text{key} \leftarrow \infty;
 6: h_v \leftarrow S.insert(v);
 7: s.key \leftarrow 0; S.insert(s);
 8: while S.is-empty() = false do
 9:
     v \leftarrow S.delete-min():
10: for all x \in V s.t. \{v, x\} \in E do
11:
               if x. key > d(v, x) then
                     S.decrease-key(h_x, d(v, x));
12:
13:
                     x. key \leftarrow d(v, x);
14:
                     x.pred \leftarrow v;
```

## Analysis of Dijkstra and Prim

Both algorithms require:

- 1 build() operation
- ▶ |V| insert() operations
- ▶ |V| delete-min() operations
- |V| is-empty() operations
- |E| decrease-key() operations

#### How good a running time can we obtain?

**8 Priority Queues** 

## **8 Priority Queues**

Operation	Binary Heap	BST	Binomial Heap	Fibonacci Heap*
build	n	$n\log n$	$n\log n$	п
minimum	1	$\log n$	$\log n$	1
is-empty	1	1	1	1
insert	$\log n$	$\log n$	$\log n$	1
delete	$\log n^{**}$	$\log n$	$\log n$	$\log n$
delete-min	$\log n$	$\log n$	$\log n$	$\log n$
decrease-key	$\log n$	$\log n$	$\log n$	1
merge	n	$n\log n$	$\log n$	1

Note that most applications use **build()** only to create an empty heap which then costs time 1.

* Fibonacci heaps only give an	1** The standard version of binary heaps is not address-
amortized guarantee.	able. Hence, it does not support a delete.

## Using Binary Heaps, Prim and Dijkstra run in time $\mathcal{O}((|V| + |E|) \log |V|).$

# Using Fibonacci Heaps, Prim and Dijkstra run in time $\mathcal{O}(|V| \log |V| + |E|)$ .

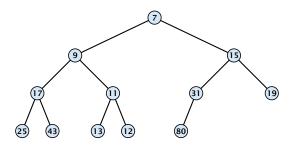

**8 Priority Queues** 

11. Apr. 2018 308/550

#### 8.1 Binary Heaps

- Nearly complete binary tree; only the last level is not full, and this one is filled from left to right.
- Heap property: A node's key is not larger than the key of one of its children.

8.1 Binary Heaps

11. Apr. 2018 309/550

#### **Binary Heaps**

#### **Operations:**

- **minimum()**: return the root-element. Time  $\mathcal{O}(1)$ .
- **is-empty():** check whether root-pointer is null. Time  $\mathcal{O}(1)$ .

8.1 Binary Heaps

11. Apr. 2018 310/550

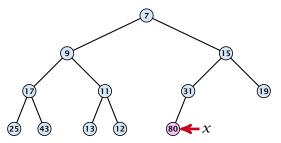

#### 8.1 Binary Heaps

Maintain a pointer to the last element *x*.

 We can compute the predecessor of x (last element when x is deleted) in time O(log n).

go up until the last edge used was a right edge. go left; go right until you reach a leaf

if you hit the root on the way up, go to the rightmost element

8.1 Binary Heaps

11. Apr. 2018 311/550

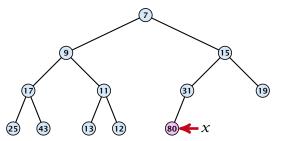

#### 8.1 Binary Heaps

Maintain a pointer to the last element *x*.

We can compute the successor of x (last element when an element is inserted) in time O(log n).

go up until the last edge used was a left edge. go right; go left until you reach a null-pointer.

if you hit the root on the way up, go to the leftmost element; insert a new element as a left child;

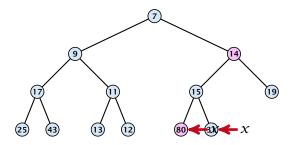

8.1 Binary Heaps

11. Apr. 2018 312/550

#### Insert

- **1.** Insert element at successor of *x*.
- 2. Exchange with parent until heap property is fulfilled.

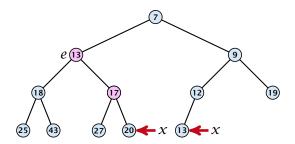

Note that an exchange can either be done by moving the data or by changing pointers. The latter method leads to an addressable priority queue.

### Delete

- Exchange the element to be deleted with the element *e* pointed to by *x*.
- **2.** Restore the heap-property for the element *e*.

At its new position e may either travel up or down in the tree (but not both directions).

### **Binary Heaps**

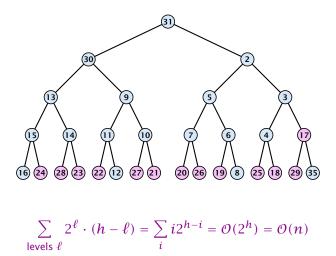

#### **Operations:**

- **minimum():** return the root-element. Time  $\mathcal{O}(1)$ .
- **is-empty():** check whether root-pointer is null. Time  $\mathcal{O}(1)$ .
- insert(k): insert at successor of x and bubble up. Time  $O(\log n)$ .
- delete(h): swap with x and bubble up or sift-down. Time O(log n).

#### **Build Heap**

We can build a heap in linear time:

8.1 Binary Heaps

11. Apr. 2018 316/550

## **Binary Heaps**

#### **Operations:**

- **minimum():** Return the root-element. Time  $\mathcal{O}(1)$ .
- **is-empty():** Check whether root-pointer is null. Time  $\mathcal{O}(1)$ .
- **insert**(*k*): Insert at *x* and bubble up. Time  $O(\log n)$ .
- delete(h): Swap with x and bubble up or sift-down. Time O(log n).
- build(x<sub>1</sub>,..., x<sub>n</sub>): Insert elements arbitrarily; then do sift-down operations starting with the lowest layer in the tree. Time O(n).

### **Binary Heaps**

The standard implementation of binary heaps is via arrays. Let A[0, ..., n-1] be an array

- The parent of *i*-th element is at position  $\lfloor \frac{i-1}{2} \rfloor$ .
- The left child of *i*-th element is at position 2i + 1.
- The right child of *i*-th element is at position 2i + 2.

Finding the successor of x is much easier than in the description on the previous slide. Simply increase or decrease x.

The resulting binary heap is not addressable. The elements don't maintain their positions and therefore there are no stable handles.

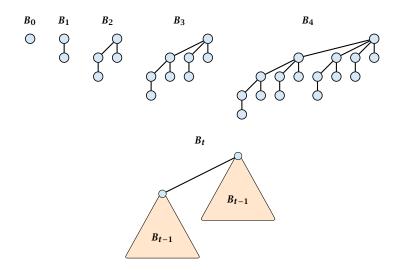

## 8.2 Binomial Heaps

Operation	Binary Heap	BST	Binomial Heap	Fibonacci Heap*
build	n	$n\log n$	$n\log n$	п
minimum	1	$\log n$	$\log n$	1
is-empty	1	1	1	1
insert	$\log n$	$\log n$	$\log n$	1
delete	$\log n^{**}$	$\log n$	$\log n$	$\log n$
delete-min	$\log n$	$\log n$	$\log n$	$\log n$
decrease-key	$\log n$	$\log n$	$\log n$	1
merge	n	$n\log n$	log n	1

8.2 Binomial Heaps

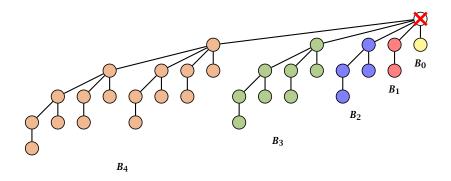

8.2 Binomial Heaps

11. Apr. 2018 320/550

#### **Properties of Binomial Trees**

- ▶  $B_k$  has  $2^k$  nodes.
- $\triangleright$   $B_k$  has height k.
- The root of  $B_k$  has degree k.
- $B_k$  has  $\binom{k}{\ell}$  nodes on level  $\ell$ .
- Deleting the root of  $B_k$  gives trees  $B_0, B_1, \ldots, B_{k-1}$ .

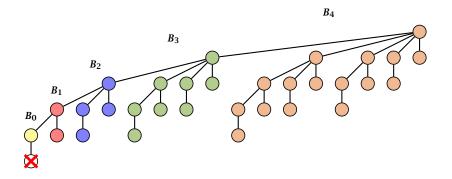

Deleting the root of  $B_5$  leaves sub-trees  $B_4$ ,  $B_3$ ,  $B_2$ ,  $B_1$ , and  $B_0$ .

8.2 Binomial Heaps

11. Apr. 2018 322/550

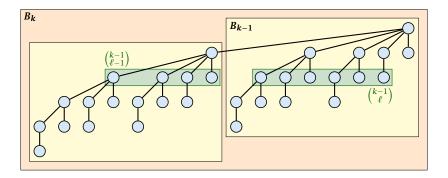

Deleting the leaf furthest from the root (in  $B_5$ ) leaves a path that connects the roots of sub-trees  $B_4$ ,  $B_3$ ,  $B_2$ ,  $B_1$ , and  $B_0$ .

8.2 Binomial Heaps

11. Apr. 2018 323/550

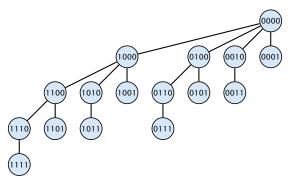

The number of nodes on level  $\ell$  in tree  $B_k$  is therefore

$$\binom{k-1}{\ell-1} + \binom{k-1}{\ell} = \binom{k}{\ell}$$

8.2 Binomial Heaps

11. Apr. 2018 324/550

The binomial tree  $B_k$  is a sub-graph of the hypercube  $H_k$ .

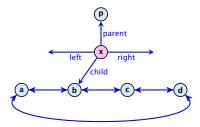

The parent of a node with label  $b_n, \ldots, b_1, b_0$  is obtained by setting the least significant 1-bit to 0.

The  $\ell$ -th level contains nodes that have  $\ell$  1's in their label.

#### 8.2 Binomial Heaps

#### How do we implement trees with non-constant degree?

- The children of a node are arranged in a circular linked list.
- A child-pointer points to an arbitrary node within the list.
- A parent-pointer points to the parent node.
- Pointers x.left and x.right point to the left and right sibling of x (if x does not have siblings then x.left = x.right = x).

8.2 Binomial Heaps

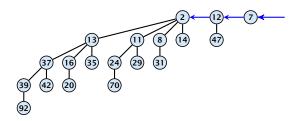

11. Apr. 2018 326/550

#### 8.2 Binomial Heaps

- Given a pointer to a node x we can splice out the sub-tree rooted at x in constant time.
- We can add a child-tree T to a node x in constant time if we are given a pointer to x and a pointer to the root of T.

#### **Binomial Heap**

In a binomial heap the keys are arranged in a collection of binomial trees.

Every tree fulfills the heap-property

There is at most one tree for every dimension/order. For example the above heap contains trees  $B_0$ ,  $B_1$ , and  $B_4$ .

8.2 Binomial Heaps

## **Binomial Heap: Merge**

Given the number n of keys to be stored in a binomial heap we can deduce the binomial trees that will be contained in the collection.

Let  $B_{k_1}$ ,  $B_{k_2}$ ,  $B_{k_3}$ ,  $k_i < k_{i+1}$  denote the binomial trees in the collection and recall that every tree may be contained at most once.

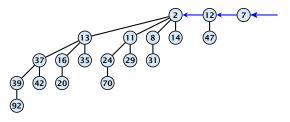

Then  $n = \sum_i 2^{k_i}$  must hold. But since the  $k_i$  are all distinct this means that the  $k_i$  define the non-zero bit-positions in the binary representation of n.

#### **Binomial Heap**

#### Properties of a heap with *n* keys:

- Let  $n = b_d b_{d-1}, \dots, b_0$  denote binary representation of n.
- The heap contains tree  $B_i$  iff  $b_i = 1$ .
- Hence, at most  $\lfloor \log n \rfloor + 1$  trees.
- The minimum must be contained in one of the roots.
- The height of the largest tree is at most  $\lfloor \log n \rfloor$ .
- The trees are stored in a single-linked list; ordered by dimension/size.

8.2 Binomial Heaps

11. Apr. 2018 330/550

## **Binomial Heap: Merge**

The merge-operation is instrumental for binomial heaps.

A merge is easy if we have two heaps with different binomial trees. We can simply merge the tree-lists.

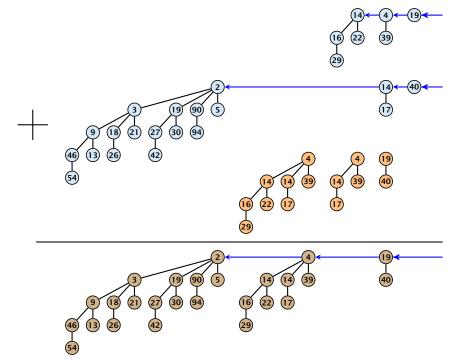

Note that we do not just do a concatenation as we want to keep the trees in the list sorted according to size.

Otherwise, we cannot do this because the merged heap is not allowed to contain two trees of the same order.

Merging two trees of the same size: Add the tree with larger root-value as a child to the other tree.

For more trees the technique is analogous to binary addition.

### 8.2 Binomial Heaps

- *S*<sub>1</sub>. merge(*S*<sub>2</sub>):
  - Analogous to binary addition.
  - Time is proportional to the number of trees in both heaps.
  - Time:  $\mathcal{O}(\log n)$ .

#### 8.2 Binomial Heaps

#### All other operations can be reduced to merge().

#### S. insert(x):

- Create a new heap S' that contains just the element x.
- Execute S. merge(S').
- Time:  $\mathcal{O}(\log n)$ .

#### S. minimum():

- Find the minimum key-value among all roots.
- Time:  $\mathcal{O}(\log n)$ .

#### S. delete-min():

- Find the minimum key-value among all roots.
- Remove the corresponding tree  $T_{\min}$  from the heap.
- Create a new heap S' that contains the trees obtained from  $T_{\min}$  after deleting the root (note that these are just  $\mathcal{O}(\log n)$  trees).
- ► Compute *S*.merge(*S*′).
- Time:  $\mathcal{O}(\log n)$ .

- S. decrease-key(handle h):
  - Decrease the key of the element pointed to by h.
  - Bubble the element up in the tree until the heap property is fulfilled.
  - Time:  $O(\log n)$  since the trees have height  $O(\log n)$ .

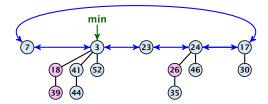

#### S. delete(handle h):

- Execute *S*. decrease-key( $h, -\infty$ ).
- **Execute** *S*. delete-min().
- Time:  $\mathcal{O}(\log n)$ .

Collection of trees that fulfill the heap property.

Structure is much more relaxed than binomial heaps.

8.3 Fibonacci Heaps

11. Apr. 2018 339/550

#### Additional implementation details:

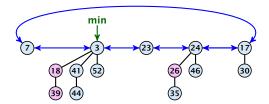

- Every node x stores its degree in a field x. degree. Note that this can be updated in constant time when adding a child to x.
- Every node stores a boolean value x.marked that specifies whether x is marked or not.

8.3 Fibonacci Heaps

#### The potential function:

- t(S) denotes the number of trees in the heap.
- m(S) denotes the number of marked nodes.
- We use the potential function  $\Phi(S) = t(S) + 2m(S)$ .

The potential is  $\Phi(S) = 5 + 2 \cdot 3 = 11$ .

8.3 Fibonacci Heaps

We assume that one unit of potential can pay for a constant amount of work, where the constant is chosen "big enough" (to take care of the constants that occur).

To make this more explicit we use *c* to denote the amount of work that a unit of potential can pay for.

8.3 Fibonacci Heaps

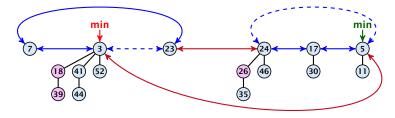

#### S. minimum()

- Access through the min-pointer.
- Actual cost  $\mathcal{O}(1)$ .
- No change in potential.
- Amortized cost  $\mathcal{O}(1)$ .

- S. merge(S')
  - Merge the root lists.
  - Adjust the min-pointer

- In the figure below the dashed edges are replaced by red edges.
- The minimum of the left heap becomes
  - the new minimum of the merged heap.

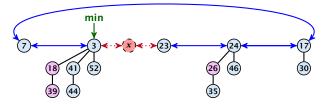

#### **Running time:**

- Actual cost  $\mathcal{O}(1)$ .
- No change in potential.
- Hence, amortized cost is  $\mathcal{O}(1)$ .

- S. insert(x)
  - Create a new tree containing x.
  - Insert x into the root-list.
  - Update min-pointer, if necessary.

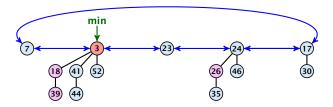

#### **Running time:**

- Actual cost  $\mathcal{O}(1)$ .
- Change in potential is +1.
- Amortized cost is c + O(1) = O(1).

 $D(\min)$  is the number of children of the node that stores the minimum.

#### S. delete-min(x)

- Delete minimum; add child-trees to heap; time: D(min) · O(1).
- Update min-pointer; time:  $(t + D(\min)) \cdot O(1)$ .

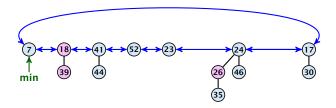

8.3 Fibonacci Heaps

 $D(\min)$  is the number of children of the node that stores the minimum.

#### S. delete-min(x)

- ► Delete minimum; add child-trees to heap; time: D(min) · O(1).
- Update min-pointer; time:  $(t + D(\min)) \cdot O(1)$ .

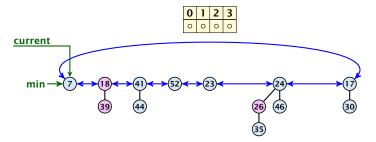

Consolidate root-list so that no roots have the same degree. Time  $t \cdot O(1)$  (see next slide).

8.3 Fibonacci Heaps

#### Consolidate:

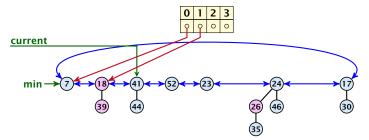

During the consolidation we traverse the root list. Whenever we discover two trees that have the same degree we merge these trees. In order to efficiently check whether two trees have the same degree, we use an array that contains for every degree value d a pointer to a tree left of the current pointer whose root has degree d (if such a tree exist).

Ernst Mayr, Harald Räcke

#### Consolidate:

8.3 Fibonacci Heaps

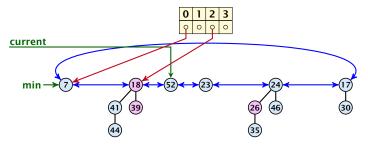

#### Consolidate:

8.3 Fibonacci Heaps

t and t' denote the number of trees before and after the delete-min() operation, respectively.  $D_n$  is an upper bound on the degree (i.e., number of children) of a tree node.

#### Actual cost for delete-min()

- At most  $D_n + t$  elements in root-list before consolidate.
- ► Actual cost for a delete-min is at most O(1) · (D<sub>n</sub> + t). Hence, there exists c<sub>1</sub> s.t. actual cost is at most c<sub>1</sub> · (D<sub>n</sub> + t).

#### Amortized cost for delete-min()

- ▶  $t' \leq D_n + 1$  as degrees are different after consolidating.
- Therefore  $\Delta \Phi \leq D_n + 1 t$ ;
- We can pay  $\mathbf{c} \cdot (\mathbf{t} D_n 1)$  from the potential decrease.
- The amortized cost is

 $c_1 \cdot (D_n + t) - \boldsymbol{c} \cdot (t - D_n - 1)$ 

 $\leq (c_1+c)D_n+(c_1-c)t+c \leq 2c(D_n+1) \leq \mathcal{O}(D_n)$ 

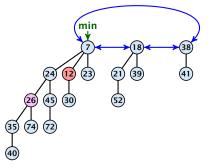

for  $\textbf{\textit{c}} \geq \textbf{\textit{c}}_1$  .

If the input trees of the consolidation procedure are binomial trees (for example only singleton vertices) then the output will be a set of distinct binomial trees, and, hence, the Fibonacci heap will be (more or less) a Binomial heap right after the consolidation.

If we do not have delete or decrease-key operations then  $D_n \leq \log n$ .

8.3 Fibonacci Heaps

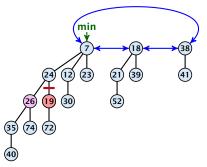

#### Case 1: decrease-key does not violate heap-property

Just decrease the key-value of element referenced by h. Nothing else to do.

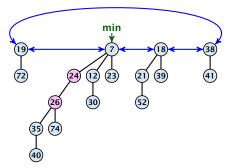

8.3 Fibonacci Heaps

11. Apr. 2018 350/550

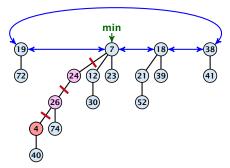

Case 2: heap-property is violated, but parent is not marked

- Decrease key-value of element x reference by h.
- If the heap-property is violated, cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Mark the (previous) parent of x (unless it's a root).

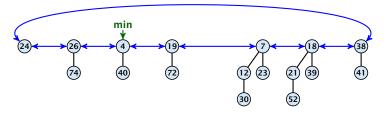

Case 2: heap-property is violated, but parent is not marked

- Decrease key-value of element x reference by h.
- If the heap-property is violated, cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Mark the (previous) parent of x (unless it's a root).

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element x reference by h.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element x reference by h.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element x reference by h.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Execute the following:

```
p \leftarrow parent[x];

while (p is marked)

pp \leftarrow parent[p];

cut of p; make it into a root; unmark it;

p \leftarrow pp;

if a is unmarked and not a not root it.
```

Marking a node can be viewed as a first step towards becoming a root. The first time *x* loses a child it is marked; the second time it loses a child it is made into a root.

if p is unmarked and not a root mark it;

#### Actual cost:

- Constant cost for decreasing the value.
- Constant cost for each of  $\ell$  cuts.
- Hence, cost is at most  $c_2 \cdot (\ell + 1)$ , for some constant  $c_2$ .

#### Amortized cost:

- $t' = t + \ell$ , as every cut creates one new root.
- ▶  $m' \le m (\ell 1) + 1 = m \ell + 2$ , since all but the first cut unmarks a node; the last cut may mark a node.
- $\bullet \ \Delta \Phi \le \ell + 2(-\ell + 2) = 4 \ell$
- Amortized cost is at most  $c_2(\ell+1) + c(4-\ell) \le (c_2-c)\ell + 4c + c_2 = O(1)$ , trees before and after m and m': number of marked nodes before and after operation.

t and t': number of

### **Delete node**

#### *H*.delete(*x*):

- decrease value of x to  $-\infty$ .
- delete-min.

#### Amortized cost: $\mathcal{O}(D_n)$

- $\mathcal{O}(1)$  for decrease-key.
- $\mathcal{O}(D_n)$  for delete-min.

#### Lemma 34

Let x be a node with degree k and let  $y_1, ..., y_k$  denote the children of x in the order that they were linked to x. Then

degree
$$(y_i) \ge \begin{cases} 0 & \text{if } i = 1\\ i - 2 & \text{if } i > 1 \end{cases}$$

The marking process is very important for the proof of this lemma. It ensures that a node can have lost at most one child since the last time it became a non-root node. When losing a first child the node gets marked; when losing the second child it is cut from the parent and made into a root.

#### Proof

- When y<sub>i</sub> was linked to x, at least y<sub>1</sub>,..., y<sub>i-1</sub> were already linked to x.
- ► Hence, at this time degree(x) ≥ i − 1, and therefore also degree(y<sub>i</sub>) ≥ i − 1 as the algorithm links nodes of equal degree only.
- Since, then y<sub>i</sub> has lost at most one child.
- Therefore, degree( $y_i$ )  $\ge i 2$ .

- Let s<sub>k</sub> be the minimum possible size of a sub-tree rooted at a node of degree k that can occur in a Fibonacci heap.
- $s_k$  monotonically increases with k
- ▶  $s_0 = 1$  and  $s_1 = 2$ .

Let x be a degree k node of size  $s_k$  and let  $y_1, \ldots, y_k$  be its children.

$$s_{k} = 2 + \sum_{i=2}^{k} \operatorname{size}(\gamma_{i})$$
$$\geq 2 + \sum_{i=2}^{k} s_{i-2}$$
$$= 2 + \sum_{i=0}^{k-2} s_{i}$$

8.3 Fibonacci Heaps

11. Apr. 2018 356/550

 $\phi = \frac{1}{2}(1 + \sqrt{5})$  denotes the *golden ratio*. Note that  $\phi^2 = 1 + \phi$ .

#### **Definition 35**

Consider the following non-standard Fibonacci type sequence:

$$F_{k} = \begin{cases} 1 & \text{if } k = 0\\ 2 & \text{if } k = 1\\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

#### Facts:

1.  $F_k \ge \phi^k$ . 2. For  $k \ge 2$ :  $F_k = 2 + \sum_{i=0}^{k-2} F_i$ .

The above facts can be easily proved by induction. From this it follows that  $s_k \ge F_k \ge \phi^k$ , which gives that the maximum degree in a Fibonacci heap is logarithmic.

k=0:  
k=1:  
k-2,k-1 
$$\rightarrow$$
 k:

[MS08] Kurt Mehlhorn, Peter Sanders: Algorithms and Data Structures — The Basic Toolbox, Springer, 2008

Binary heaps are covered in [CLRS90] in combination with the heapsort algorithm in Chapter 6. Fibonacci heaps are covered in detail in Chapter 19. Problem 19-2 in this chapter introduces Binomial heaps.

Chapter 6 in [MS08] covers Priority Queues. Chapter 6.2.2 discusses Fibonacci heaps. Binomial heaps are dealt with in Exercise 6.11.

8.3 Fibonacci Heaps

11. Apr. 2018 359/550

Union Find Data Structure  $\mathcal{P}$ : Maintains a partition of disjoint sets over elements.

- P. makeset(x): Given an element x, adds x to the data-structure and creates a singleton set that contains only this element. Returns a locator/handle for x in the data-structure.
- P. find(x): Given a handle for an element x; find the set that contains x. Returns a representative/identifier for this set.
- ▶  $\mathcal{P}$ . union(x, y): Given two elements x, and y that are currently in sets  $S_x$  and  $S_y$ , respectively, the function replaces  $S_x$  and  $S_y$  by  $S_x \cup S_y$  and returns an identifier for the new set.

### **Applications:**

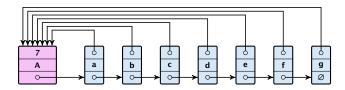

- Keep track of the connected components of a dynamic graph that changes due to insertion of nodes and edges.
- Kruskals Minimum Spanning Tree Algorithm

Algorithm 16 Kruskal-MST(G = (V, E), w)1:  $A \leftarrow \emptyset$ ;2: for all  $v \in V$  do3:  $v. set \leftarrow \mathcal{P}.$  makeset(v. label)4: sort edges in non-decreasing order of weight w5: for all  $(u, v) \in E$  in non-decreasing order do6: if  $\mathcal{P}.$  find(u. set)  $\neq \mathcal{P}.$  find(v. set) then7:  $A \leftarrow A \cup \{(u, v)\}$ 8:  $\mathcal{P}.$  union(u. set, v. set)

- The elements of a set are stored in a list; each node has a backward pointer to the head.
- The head of the list contains the identifier for the set and a field that stores the size of the set.

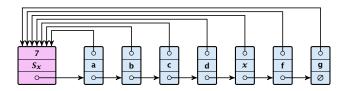

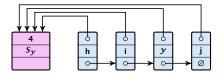

- makeset(x) can be performed in constant time.
- find(x) can be performed in constant time.

### union(x, y)

- Determine sets  $S_x$  and  $S_y$ .
- Traverse the smaller list (say S<sub>y</sub>), and change all backward pointers to the head of list S<sub>x</sub>.
- lnsert list  $S_y$  at the head of  $S_x$ .
- Adjust the size-field of list  $S_{\chi}$ .
- Time:  $\min\{|S_x|, |S_y|\}$ .

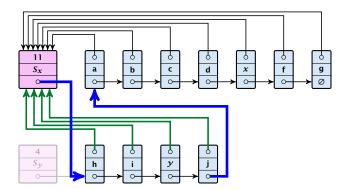

9 Union Find

11. Apr. 2018 364/550

9 Union Find

11. Apr. 2018 364/550

### **Running times:**

- ▶ find(x): constant
- makeset(x): constant
- ► union(x, y): O(n), where n denotes the number of elements contained in the set system.

### Lemma 36

The list implementation for the ADT union find fulfills the following amortized time bounds:

- ▶ find(x):  $\mathcal{O}(1)$ .
- makeset(x):  $\mathcal{O}(\log n)$ .
- union(x, y):  $\mathcal{O}(1)$ .

# The Accounting Method for Amortized Time Bounds

- There is a bank account for every element in the data structure.
- Initially the balance on all accounts is zero.
- Whenever for an operation the amortized time bound exceeds the actual cost, the difference is credited to some bank accounts of elements involved.
- Whenever for an operation the actual cost exceeds the amortized time bound, the difference is charged to bank accounts of some of the elements involved.
- If we can find a charging scheme that guarantees that balances always stay positive the amortized time bounds are proven.

- For an operation whose actual cost exceeds the amortized cost we charge the excess to the elements involved.
- In total we will charge at most O(log n) to an element (regardless of the request sequence).
- For each element a makeset operation occurs as the first operation involving this element.
- We inflate the amortized cost of the makeset-operation to Θ(log n), i.e., at this point we fill the bank account of the element to Θ(log n).
- Later operations charge the account but the balance never drops below zero.

**makeset**(*x*): The actual cost is O(1). Due to the cost inflation the amortized cost is  $O(\log n)$ .

**find**(x): For this operation we define the amortized cost and the actual cost to be the same. Hence, this operation does not change any accounts. Cost: O(1).

### union(x, y):

- If  $S_x = S_y$  the cost is constant; no bank accounts change.
- Otw. the actual cost is  $\mathcal{O}(\min\{|S_{\chi}|, |S_{\mathcal{Y}}|\})$ .
- Assume wlog. that S<sub>x</sub> is the smaller set; let c denote the hidden constant, i.e., the actual cost is at most c · |S<sub>x</sub>|.
- Charge *c* to every element in set  $S_{\chi}$ .

### Lemma 37

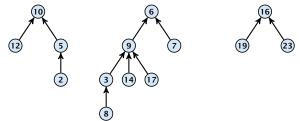

An element is charged at most  $\lfloor \log_2 n \rfloor$  times, where *n* is the total number of elements in the set system.

### Proof.

Whenever an element x is charged the number of elements in x's set doubles. This can happen at most  $\lfloor \log n \rfloor$  times.

- Maintain nodes of a set in a tree.
- The root of the tree is the label of the set.
- Only pointer to parent exists; we cannot list all elements of a given set.
- Example:

Set system {2, 5, 10, 12}, {3, 6, 7, 8, 9, 14, 17}, {16, 19, 23}.

החוחר	Ernst Mayr, Harald	
	Ernst Mayr, Harald	Räcke

9 Union Find

11. Apr. 2018 371/550

### makeset(x)

- Create a singleton tree. Return pointer to the root.
- ▶ Time: *O*(1).

find(x)

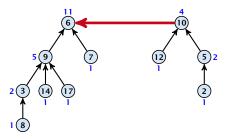

- Start at element x in the tree. Go upwards until you reach the root.
- Time: O(level(x)), where level(x) is the distance of element x to the root in its tree. Not constant.

To support union we store the size of a tree in its root.

union(x, y)

- ▶ Perform  $a \leftarrow \operatorname{find}(x)$ ;  $b \leftarrow \operatorname{find}(y)$ . Then:  $\operatorname{link}(a, b)$ .
- link(a, b) attaches the smaller tree as the child of the larger.
- In addition it updates the size-field of the new root.

Time: constant for link(a, b) plus two find-operations.

9 Union Find

11. Apr. 2018 373/550

### Lemma 38

The running time (non-amortized!!!) for find(x) is  $O(\log n)$ .

### Proof.

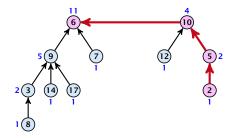

- When we attach a tree with root c to become a child of a tree with root p, then size(p) ≥ 2 size(c), where size denotes the value of the size-field right after the operation.
- After that the value of size(c) stays fixed, while the value of size(p) may still increase.
- Hence, at any point in time a tree fulfills size(p) ≥ 2 size(c), for any pair of nodes (p, c), where p is a parent of c.

# Path Compression

find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

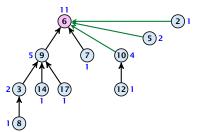

Note that the size-fields now only give an upper bound on the size of a sub-tree.

# Path Compression

find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

One could change the algorithm to update the size-fields. This could be done without asymptotically affecting the running time.

However, the only size-field that is actually required is the field at the root, which is always correct.

We will only use the other sizefields for the proof of Theorem 41.

Note that the size-fields now only give an upper bound on the size of a sub-tree. Asymptotically the cost for a find-operation does not increase due to the path compression heuristic.

However, for a worst-case analysis there is no improvement on the running time. It can still happen that a find-operation takes time  $O(\log n)$ .

### **Definitions:**

size(v) = the number of nodes that were in the sub-tree rooted at v when v became the child of another node (or the number of nodes if v is the root).

Note that this is the same as the size of v's subtree in the case that there are no find-operations.

- ► rank(v) =  $\lfloor \log(size(v)) \rfloor$ .
- ►  $\Rightarrow$  size $(v) \ge 2^{\operatorname{rank}(v)}$ .

### Lemma 39

The rank of a parent must be strictly larger than the rank of a child.

### Lemma 40

There are at most  $n/2^s$  nodes of rank s.

Proof.

- Let's say a node v sees node x if v is in x's sub-tree at the time that x becomes a child.
- A node v sees at most one node of rank s during the running time of the algorithm.
- This holds because the rank-sequence of the roots of the different trees that contain v during the running time of the algorithm is a strictly increasing sequence.
- Hence, every node sees at most one rank s node, but every rank s node is seen by at least 2<sup>s</sup> different nodes.

We define

$$\operatorname{tow}(i) := \begin{cases} 1 & \text{if } i = 0\\ 2^{\operatorname{tow}(i-1)} & \text{otw.} \end{cases} \quad \operatorname{tow}(i) = 2^{2^{2^{2^{2^{2}}}}} i \text{ times}$$

and

$$\log^*(n) := \min\{i \mid \text{tow}(i) \ge n\} .$$

### Theorem 41

Union find with path compression fulfills the following amortized running times:

- makeset(x) :  $\mathcal{O}(\log^*(n))$
- find(x) :  $\mathcal{O}(\log^*(n))$
- union(x, y) :  $\mathcal{O}(\log^*(n))$

In the following we assume  $n \ge 2$ .

### rank-group:

- A node with rank rank(v) is in rank group  $log^*(rank(v))$ .
- The rank-group g = 0 contains only nodes with rank 0 or rank 1.
- A rank group  $g \ge 1$  contains ranks  $tow(g-1) + 1, \dots, tow(g)$ .
- The maximum non-empty rank group is  $\log^*(\lfloor \log n \rfloor) \le \log^*(n) 1$  (which holds for  $n \ge 2$ ).
- Hence, the total number of rank-groups is at most  $\log^* n$ .

### Accounting Scheme:

- create an account for every find-operation
- create an account for every node v

The cost for a find-operation is equal to the length of the path traversed. We charge the cost for going from v to parent[v] as follows:

- If parent[v] is the root we charge the cost to the find-account.
- If the group-number of rank(v) is the same as that of rank(parent[v]) (before starting path compression) we charge the cost to the node-account of v.
- Otherwise we charge the cost to the find-account.

### **Observations:**

- ► A find-account is charged at most log\*(n) times (once for the root and at most log\*(n) - 1 times when increasing the rank-group).
- After a node v is charged its parent-edge is re-assigned. The rank of the parent strictly increases.
- ► After some charges to v the parent will be in a larger rank-group. ⇒ v will never be charged again.
- The total charge made to a node in rank-group g is at most tow(g) - tow(g − 1) − 1 ≤ tow(g).

### What is the total charge made to nodes?

The total charge is at most

 $\sum_{g} n(g) \cdot \operatorname{tow}(g)$  ,

where n(g) is the number of nodes in group g.

For  $g \ge 1$  we have

$$n(g) \le \sum_{s=\text{tow}(g-1)+1}^{\text{tow}(g)} \frac{n}{2^s} \le \sum_{s=\text{tow}(g-1)+1}^{\infty} \frac{n}{2^s}$$
$$= \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\infty} \frac{1}{2^s} = \frac{n}{2^{\text{tow}(g-1)+1}} \cdot 2$$
$$= \frac{n}{2^{\text{tow}(g-1)}} = \frac{n}{\text{tow}(g)} .$$

Hence,

$$\sum_{g} n(g) \operatorname{tow}(g) \le n(0) \operatorname{tow}(0) + \sum_{g \ge 1} n(g) \operatorname{tow}(g) \le n \log^*(n)$$

9 Union Find

11. Apr. 2018 384/550 Without loss of generality we can assume that all makeset-operations occur at the start.

This means if we inflate the cost of makeset to  $\log^* n$  and add this to the node account of v then the balances of all node accounts will sum up to a positive value (this is sufficient to obtain an amortized bound).

The analysis is not tight. In fact it has been shown that the amortized time for the union-find data structure with path compression is  $\mathcal{O}(\alpha(m, n))$ , where  $\alpha(m, n)$  is the inverse Ackermann function which grows a lot lot slower than  $\log^* n$ . (Here, we consider the average running time of m operations on at most n elements).

There is also a lower bound of  $\Omega(\alpha(m, n))$ .

$$A(x, y) = \begin{cases} y+1 & \text{if } x = 0\\ A(x-1, 1) & \text{if } y = 0\\ A(x-1, A(x, y-1)) & \text{otw.} \end{cases}$$

 $\alpha(m, n) = \min\{i \ge 1 : A(i, \lfloor m/n \rfloor) \ge \log n\}$ 

• 
$$A(0, y) = y + 1$$
  
•  $A(1, y) = y + 2$   
•  $A(2, y) = 2y + 3$   
•  $A(3, y) = 2^{y+3} - 3$   
•  $A(4, y) = \underbrace{2^{2^{2^2}}}_{y+3 \text{ times}} -3$

Union find data structures are discussed in Chapter 21 of [CLRS90b] and [CLRS90c] and in Chapter 22 of [CLRS90a]. The analysis of union by rank with path compression can be found in [CLRS90a] but neither in [CLRS90b] in nor in [CLRS90c]. The latter books contains a more involved analysis that gives a better bound than  $\mathcal{O}(\log^* n)$ .

A description of the  $O(\log^*)$ -bound can also be found in Chapter 4.8 of [AHU74].

# Part IV

# **Flows and Cuts**

11. Apr. 2018 388/550 The following slides are partially based on slides by Kevin Wayne.

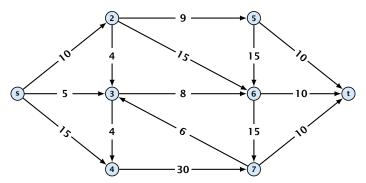

11. Apr. 2018 389/550

# **10 Introduction**

#### **Flow Network**

- directed graph G = (V, E); edge capacities c(e)
- two special nodes: source s; target t;
- no edges entering s or leaving t;
- at least for now: no parallel edges;

**10 Introduction** 

11. Apr. 2018 390/550

## Cuts

#### **Definition 42**

An (s, t)-cut in the graph G is given by a set  $A \subset V$  with  $s \in A$ and  $t \in V \setminus A$ .

#### **Definition 43**

The capacity of a cut A is defined as

$$\operatorname{cap}(A, V \setminus A) := \sum_{e \in \operatorname{out}(A)} c(e) ,$$

where out(A) denotes the set of edges of the form  $A \times V \setminus A$ (i.e. edges leaving A).

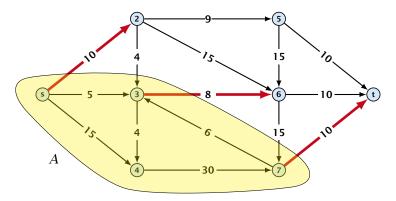

# **Minimum Cut Problem:** Find an (s, t)-cut with minimum capacity.

**10 Introduction** 

### Cuts

#### Example 44

The capacity of the cut is  $cap(A, V \setminus A) = 28$ .

5000	Ernst Mayr, Harald	
	Ernst Mayr, Harald	Räcke

**10 Introduction** 

11. Apr. 2018 392/550

#### **Definition 45**

An (s, t)-flow is a function  $f : E \mapsto \mathbb{R}^+$  that satisfies

1. For each edge *e* 

 $0 \leq f(e) \leq c(e)$  .

(capacity constraints)

**2.** For each  $v \in V \setminus \{s, t\}$ 

(flow conservation constraints)

**10 Introduction** 

11. Apr. 2018 393/550

### **Definition 46** The value of an (s, t)-flow f is defined as

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(s)} f(e)$$
.

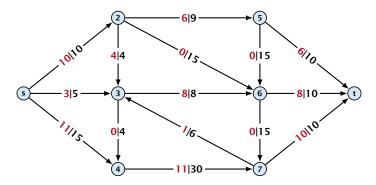

# **Maximum Flow Problem:** Find an (s, t)-flow with maximum value.

**10 Introduction** 

11. Apr. 2018 394/550

#### Example 47

The value of the flow is val(f) = 24.

**10 Introduction** 

11. Apr. 2018 395/550

#### Lemma 48 (Flow value lemma)

Let f be a flow, and let  $A \subseteq V$  be an (s,t)-cut. Then the net-flow across the cut is equal to the amount of flow leaving s, i.e.,

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(A)} f(e) - \sum_{e \in \operatorname{into}(A)} f(e)$$
.

**10 Introduction** 

11. Apr. 2018 396/550

#### Proof.

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(s)} f(e)$$
$$= \sum_{e \in \operatorname{out}(s)} f(e) + \sum_{v \in A \setminus \{s\}} \left( \sum_{e \in \operatorname{out}(v)} f(e) - \sum_{e \in \operatorname{in}(v)} f(e) \right)$$
$$= \sum_{e \in \operatorname{out}(A)} f(e) - \sum_{e \in \operatorname{into}(A)} f(e)$$

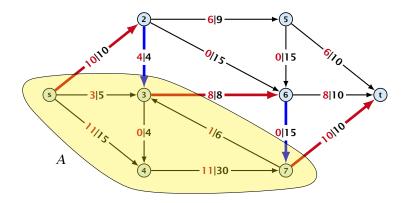

The last equality holds since every edge with both end-points in A contributes negatively as well as positively to the sum in Line 2. The only edges whose contribution doesn't cancel out are edges leaving or entering A.

**10 Introduction** 

11. Apr. 2018 397/550

#### Example 49

**10 Introduction** 

11. Apr. 2018 398/550

#### **Corollary 50**

Let f be an (s,t)-flow and let A be an (s,t)-cut, such that

 $\operatorname{val}(f) = \operatorname{cap}(A, V \setminus A).$ 

Then f is a maximum flow.

1

#### **Proof.**

Suppose that there is a flow f' with larger value. Then

$$cap(A, V \setminus A) < val(f')$$

$$= \sum_{e \in out(A)} f'(e) - \sum_{e \in into(A)} f'(e)$$

$$\leq \sum_{e \in out(A)} f'(e)$$

$$\leq cap(A, V \setminus A)$$

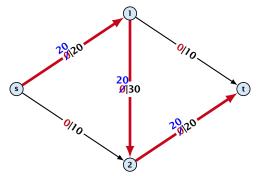

10 Introduction

11. Apr. 2018 399/550

### Greedy-algorithm:

- **•** start with f(e) = 0 everywhere
- ▶ find an *s*-*t* path with *f*(*e*) < *c*(*e*) on every edge
- augment flow along the path
- repeat as long as possible

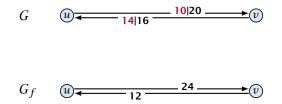

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 400/550

# **The Residual Graph**

From the graph G = (V, E, c) and the current flow f we construct an auxiliary graph  $G_f = (V, E_f, c_f)$  (the residual graph):

- Suppose the original graph has edges e<sub>1</sub> = (u, v), and e<sub>2</sub> = (v, u) between u and v.
- $G_f$  has edge  $e'_1$  with capacity  $\max\{0, c(e_1) f(e_1) + f(e_2)\}$ and  $e'_2$  with with capacity  $\max\{0, c(e_2) - f(e_2) + f(e_1)\}$ .

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 401/550

### **Definition 51**

An augmenting path with respect to flow f, is a path from s to t in the auxiliary graph  $G_f$  that contains only edges with non-zero capacity.

Algorithm 1 FordFulkerson(G = (V, E, c))

- 1: Initialize  $f(e) \leftarrow 0$  for all edges.
- 2: while  $\exists$  augmenting path p in  $G_f$  do
- 3: augment as much flow along p as possible.

Animation for augmenting path algorithms is only available in the lecture version of the slides.

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 403/550

#### Theorem 52

A flow f is a maximum flow **iff** there are no augmenting paths.

### Theorem 53

The value of a maximum flow is equal to the value of a minimum cut.

### Proof.

Let f be a flow. The following are equivalent:

- **1.** There exists a cut *A* such that  $val(f) = cap(A, V \setminus A)$ .
- **2.** Flow f is a maximum flow.
- 3. There is no augmenting path w.r.t. f.

 $1. \Rightarrow 2.$ 

This we already showed.

 $2. \Rightarrow 3.$ 

If there were an augmenting path, we could improve the flow. Contradiction.

 $3. \Rightarrow 1.$ 

- Let f be a flow with no augmenting paths.
- Let A be the set of vertices reachable from s in the residual graph along non-zero capacity edges.
- Since there is no augmenting path we have  $s \in A$  and  $t \notin A$ .

$$\operatorname{val}(f) = \sum_{e \in \operatorname{out}(A)} f(e) - \sum_{e \in \operatorname{into}(A)} f(e)$$
$$= \sum_{e \in \operatorname{out}(A)} c(e)$$
$$= \operatorname{cap}(A, V \setminus A)$$

This finishes the proof.

Here the first equality uses the flow value lemma, and the second exploits the fact that the flow along incoming edges must be 0 as the residual graph does not have edges leaving A.

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 406/550

# Analysis

Assumption: All capacities are integers between 1 and C.

Invariant:

Every flow value f(e) and every residual capacity  $c_f(e)$  remains integral troughout the algorithm.

11.1 The Generic Augmenting Path Algorithm

#### Lemma 54

The algorithm terminates in at most  $val(f^*) \le nC$  iterations, where  $f^*$  denotes the maximum flow. Each iteration can be implemented in time O(m). This gives a total running time of O(nmC).

#### **Theorem 55**

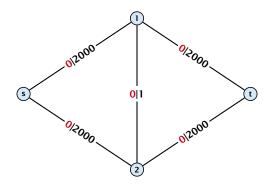

If all capacities are integers, then there exists a maximum flow for which every flow value f(e) is integral.

11.1 The Generic Augmenting Path Algorithm

# A Bad Input

Problem: The running time may not be polynomial.

#### Question:

Can we tweak the algorithm so that the running time is polynomial in the input length?

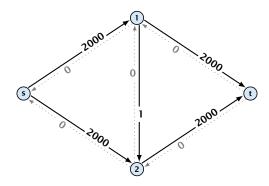

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 409/550

# A Bad Input

Problem: The running time may not be polynomial.

Question:

Can we tweak the algorithm so that the running time is polynomial in the input length?

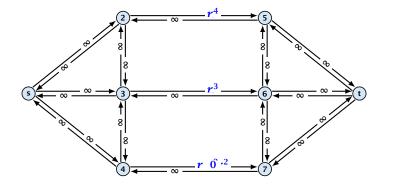

11.1 The Generic Augmenting Path Algorithm

# **A Pathological Input**

Let 
$$r = \frac{1}{2}(\sqrt{5} - 1)$$
. Then  $r^{n+2} = r^n - r^{n+1}$ 

Running time may be infinite!!! See the lecture-version of the slides for the animation.

11.1 The Generic Augmenting Path Algorithm

11. Apr. 2018 411/550

#### How to choose augmenting paths?

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

#### Several possibilities:

- Choose path with maximum bottleneck capacity.
- Choose path with sufficiently large bottleneck capacity.
- Choose the shortest augmenting path.

# **Overview: Shortest Augmenting Paths**

### **Lemma 56** *The length of the shortest augmenting path never decreases.*

# **Lemma 57** After at most $\mathcal{O}(m)$ augmentations, the length of the shortest augmenting path strictly increases.

# **Overview: Shortest Augmenting Paths**

These two lemmas give the following theorem:

### Theorem 58

The shortest augmenting path algorithm performs at most O(mn) augmentations. This gives a running time of  $O(m^2n)$ .

#### Proof.

- ► We can find the shortest augmenting paths in time O(m) via BFS.
- $\mathcal{O}(m)$  augmentations for paths of exactly k < n edges.

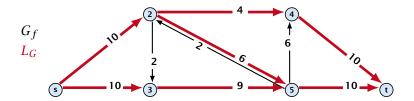

# **Shortest Augmenting Paths**

Define the level  $\ell(v)$  of a node as the length of the shortest *s*-*v* path in  $G_f$ .

Let  $L_G$  denote the subgraph of the residual graph  $G_f$  that contains only those edges (u, v) with  $\ell(v) = \ell(u) + 1$ .

A path P is a shortest s-u path in  $G_f$  if it is a an s-u path in  $L_G$ .

11.2 Shortest Augmenting Paths

11. Apr. 2018 415/550 In the following we assume that the residual graph  $G_f$  does not contain zero capacity edges.

This means, we construct it in the usual sense and then delete edges of zero capacity.

# **Shortest Augmenting Path**

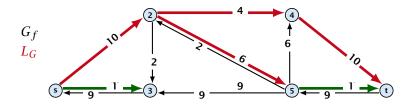

#### First Lemma:

The length of the shortest augmenting path never decreases.

After an augmentation  $G_f$  changes as follows:

- Bottleneck edges on the chosen path are deleted.
- Back edges are added to all edges that don't have back edges so far.

These changes cannot decrease the distance between s and t.

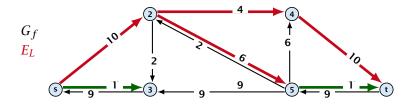

## **Shortest Augmenting Path**

**Second Lemma:** After at most m augmentations the length of the shortest augmenting path strictly increases.

Let  $E_L$  denote the set of edges in graph  $L_G$  at the beginning of a round when the distance between s and t is k.

An *s*-*t* path in  $G_f$  that uses edges not in  $E_L$  has length larger than k, even when considering edges added to  $G_f$  during the round.

In each augmentation one edge is deleted from  $E_L$ .

# **Shortest Augmenting Paths**

#### **Theorem 59**

The shortest augmenting path algorithm performs at most  $\mathcal{O}(mn)$  augmentations. Each augmentation can be performed in time  $\mathcal{O}(m)$ .

### Theorem 60 (without proof)

There exist networks with  $m = \Theta(n^2)$  that require  $\mathcal{O}(mn)$  augmentations, when we restrict ourselves to only augment along shortest augmenting paths.

#### Note:

There always exists a set of m augmentations that gives a maximum flow (why?).

When sticking to shortest augmenting paths we cannot improve (asymptotically) on the number of augmentations.

However, we can improve the running time to  $\mathcal{O}(mn^2)$  by improving the running time for finding an augmenting path (currently we assume  $\mathcal{O}(m)$  per augmentation for this).

# **Shortest Augmenting Paths**

We maintain a subset  $E_L$  of the edges of  $G_f$  with the guarantee that a shortest *s*-*t* path using only edges from  $E_L$  is a shortest augmenting path.

With each augmentation some edges are deleted from  $E_L$ .

When  $E_L$  does not contain an *s*-*t* path anymore the distance between *s* and *t* strictly increases.

Note that  $E_L$  is not the set of edges of the level graph but a subset of level-graph edges.

Suppose that the initial distance between s and t in  $G_f$  is k.

 $E_L$  is initialized as the level graph  $L_G$ .

Perform a DFS search to find a path from s to t using edges from  $E_L$ .

Either you find t after at most n steps, or you end at a node v that does not have any outgoing edges.

You can delete incoming edges of v from  $E_L$ .

Let a phase of the algorithm be defined by the time between two augmentations during which the distance between s and t strictly increases.

```
Initializing E_L for the phase takes time \mathcal{O}(m).
```

The total cost for searching for augmenting paths during a phase is at most  $\mathcal{O}(mn)$ , since every search (successful (i.e., reaching *t*) or unsuccessful) decreases the number of edges in  $E_L$  and takes time  $\mathcal{O}(n)$ .

The total cost for performing an augmentation during a phase is only  $\mathcal{O}(n)$ . For every edge in the augmenting path one has to update the residual graph  $G_f$  and has to check whether the edge is still in  $E_L$  for the next search.

There are at most n phases. Hence, total cost is  $O(mn^2)$ .

#### How to choose augmenting paths?

- We need to find paths efficiently.
- We want to guarantee a small number of iterations.

#### Several possibilities:

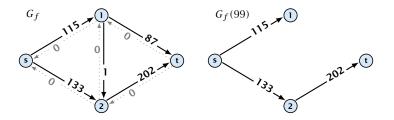

- Choose path with maximum bottleneck capacity.
- Choose path with sufficiently large bottleneck capacity.
- Choose the shortest augmenting path.

# **Capacity Scaling**

### Intuition:

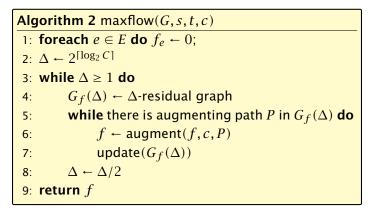

- Choosing a path with the highest bottleneck increases the flow as much as possible in a single step.
- Don't worry about finding the exact bottleneck.
- Maintain scaling parameter  $\Delta$ .
- $G_f(\Delta)$  is a sub-graph of the residual graph  $G_f$  that contains only edges with capacity at least  $\Delta$ .

11.3 Capacity Scaling

11. Apr. 2018 425/550

## Assumption:

All capacities are integers between 1 and C.

## Invariant:

All flows and capacities are/remain integral throughout the algorithm.

## Correctness:

The algorithm computes a maxflow:

- because of integrality we have  $G_f(1) = G_f$
- therefore after the last phase there are no augmenting paths anymore
- this means we have a maximum flow.

**Lemma 61** *There are*  $\lceil \log C \rceil + 1$  *iterations over*  $\Delta$ . **Proof:** obvious.

## Lemma 62

Let f be the flow at the end of a  $\Delta$ -phase. Then the maximum flow is smaller than  $val(f) + m\Delta$ .

Proof: less obvious, but simple:

- There must exist an *s*-*t* cut in  $G_f(\Delta)$  of zero capacity.
- In  $G_f$  this cut can have capacity at most  $m\Delta$ .
- This gives me an upper bound on the flow that I can still add.

## Lemma 63

There are at most 2m augmentations per scaling-phase.

Proof:

- Let f be the flow at the end of the previous phase.
- $\operatorname{val}(f^*) \leq \operatorname{val}(f) + 2m\Delta$
- Each augmentation increases flow by  $\Delta$ .

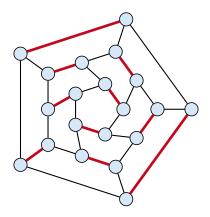

**Theorem 64** 

We need  $\mathcal{O}(m \log C)$  augmentations. The algorithm can be implemented in time  $\mathcal{O}(m^2 \log C)$ .

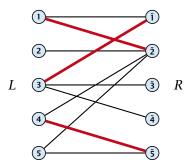

# Matching

- lnput: undirected graph G = (V, E).
- $M \subseteq E$  is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

# **Bipartite Matching**

- ▶ Input: undirected, bipartite graph  $G = (L \uplus R, E)$ .
- $M \subseteq E$  is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

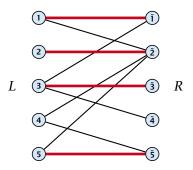

12.1 Matching

11. Apr. 2018 431/550

# **Bipartite Matching**

- ▶ Input: undirected, bipartite graph  $G = (L \uplus R, E)$ .
- $M \subseteq E$  is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

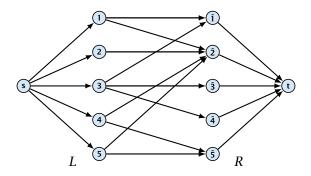

12.1 Matching

11. Apr. 2018 432/550

## **Maxflow Formulation**

- ▶ Input: undirected, bipartite graph  $G = (L \uplus R \uplus \{s, t\}, E')$ .
- Direct all edges from L to R.
- Add source s and connect it to all nodes on the left.
- Add *t* and connect all nodes on the right to *t*.
- All edges have unit capacity.

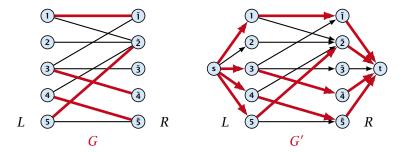

12.1 Matching

11. Apr. 2018 433/550

# Proof

## Max cardinality matching in $G \leq$ value of maxflow in G'

- Given a maximum matching *M* of cardinality *k*.
- Consider flow f that sends one unit along each of k paths.
- f is a flow and has cardinality k.

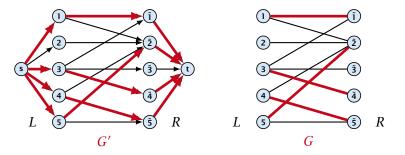

12.1 Matching

11. Apr. 2018 434/550

# Proof

## Max cardinality matching in $G \ge$ value of maxflow in G'

- Let f be a maxflow in G' of value k
- Integrality theorem  $\Rightarrow k$  integral; we can assume f is 0/1.
- Consider M= set of edges from L to R with f(e) = 1.
- Each node in *L* and *R* participates in at most one edge in *M*.
- ▶ |M| = k, as the flow must use at least k middle edges.

12.1 Matching

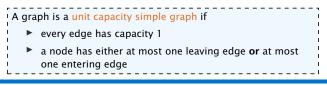

11. Apr. 2018 435/550

# 12.1 Matching

## Which flow algorithm to use?

- Generic augmenting path:  $\mathcal{O}(m \operatorname{val}(f^*)) = \mathcal{O}(mn)$ .
- Capacity scaling:  $\mathcal{O}(m^2 \log C) = \mathcal{O}(m^2)$ .
- Shortest augmenting path:  $\mathcal{O}(mn^2)$ .

For unit capacity simple graphs shortest augmenting path can be implemented in time  $\mathcal{O}(m\sqrt{n})$ .

team	wins	losses	remaining games			
i	$w_i$	$\ell_i$	Atl	Phi	NY	Mon
Atlanta	83	71	-	1	6	1
Philadelphia	80	79	1	-	0	2
New York	78	78	6	0	_	0
Montreal	77	82	1	2	0	-

#### Which team can end the season with most wins?

- Montreal is eliminated, since even after winning all remaining games there are only 80 wins.
- But also Philadelphia is eliminated. Why?

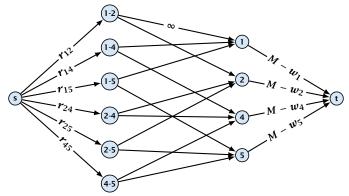

### Formal definition of the problem:

- Given a set *S* of teams, and one specific team  $z \in S$ .
- Team x has already won  $w_x$  games.
- Team x still has to play team y,  $r_{xy}$  times.
- Does team z still have a chance to finish with the most number of wins.

Flow network for z = 3. *M* is number of wins Team 3 can still obtain.

**Idea.** Distribute the results of remaining games in such a way that no team gets too many wins.

12.2 Baseball Elimination

11. Apr. 2018 439/550

# **Certificate of Elimination**

Let  $T \subseteq S$  be a subset of teams. Define

$$w(T) := \sum_{i \in T} w_i, \qquad r(T) := \sum_{i,j \in T, i < j} r_{ij}$$
  
wins of  
teams in T remaining games  
among teams in T

If  $\frac{w(T)+r(T)}{|T|} > M$  then one of the teams in T will have more than M wins in the end. A team that can win at most M games is therefore eliminated.

#### **Theorem 65**

A team z is eliminated if and only if the flow network for z does not allow a flow of value  $\sum_{ij \in S \setminus \{z\}, i < j} \gamma_{ij}$ .

## Proof (⇐)

- Consider the mincut A in the flow network. Let T be the set of team-nodes in A.
- If for node x-y not both team-nodes x and y are in T, then x-y ∉ A as otw. the cut would cut an infinite capacity edge.
- We don't find a flow that saturates all source edges:

 $r(S \setminus \{z\}) > \operatorname{cap}(A, V \setminus A)$   $\geq \sum_{i < j: i \notin T \lor j \notin T} r_{ij} + \sum_{i \in T} (M - w_i)$  $\geq r(S \setminus \{z\}) - r(T) + |T|M - w(T)$ 

► This gives M < (w(T) + r(T))/|T|, i.e., z is eliminated.

Proof (⇒)

- Suppose we have a flow that saturates all source edges.
- We can assume that this flow is integral.
- For every pairing x-y it defines how many games team x and team y should win.
- The flow leaving the team-node x can be interpreted as the additional number of wins that team x will obtain.
- This is less than  $M w_{\chi}$  because of capacity constraints.
- Hence, we found a set of results for the remaining games, such that no team obtains more than M wins in total.
- Hence, team *z* is not eliminated.

# **Project Selection**

### Project selection problem:

- Set P of possible projects. Project v has an associated profit p<sub>v</sub> (can be positive or negative).
- Some projects have requirements (taking course EA2 requires course EA1).
- Dependencies are modelled in a graph. Edge (u, v) means "can't do project u without also doing project v."
- A subset A of projects is feasible if the prerequisites of every project in A also belong to A.

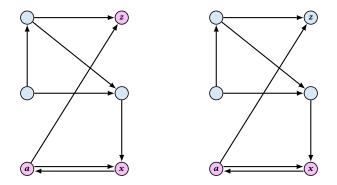

**Goal:** Find a feasible set of projects that maximizes the profit.

# **Project Selection**

## The prerequisite graph:

- $\{x, a, z\}$  is a feasible subset.
- $\{x, a\}$  is infeasible.

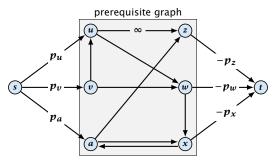

12.3 Project Selection

11. Apr. 2018 444/550

# **Project Selection**

## Mincut formulation:

- Edges in the prerequisite graph get infinite capacity.
- Add edge (s, v) with capacity pv for nodes v with positive profit.
- Create edge (v, t) with capacity -pv for nodes v with negative profit.

12.3 Project Selection

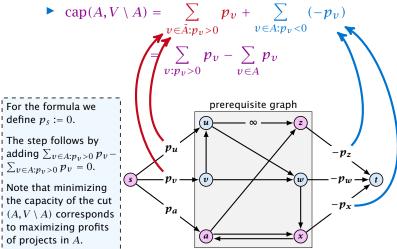

11. Apr. 2018 445/550

#### **Theorem 66**

A is a mincut if  $A \setminus \{s\}$  is the optimal set of projects.

### Proof.

► *A* is feasible because of capacity infinity edges.

## **Definition 67**

An (s, t)-preflow is a function  $f : E \mapsto \mathbb{R}^+$  that satisfies

1. For each edge *e* 

$$0 \leq f(e) \leq c(e)$$
 .

(capacity constraints)

**2.** For each  $v \in V \setminus \{s, t\}$ 

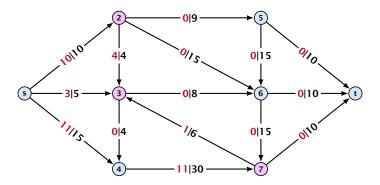

$$\sum_{e \in \text{out}(v)} f(e) \le \sum_{e \in \text{into}(v)} f(e) \ .$$

13.1 Generic Push Relabel

11. Apr. 2018 447/550

### Example 68

A node that has  $\sum_{e \in \text{out}(v)} f(e) < \sum_{e \in \text{into}(v)} f(e)$  is called an active node.

13.1 Generic Push Relabel

11. Apr. 2018 448/550

## Definition:

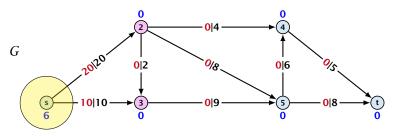

A labelling is a function  $\ell: V \to \mathbb{N}$ . It is valid for preflow f if

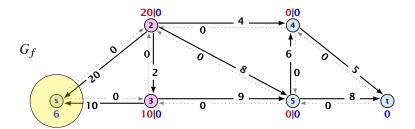

- ▶  $\ell(u) \leq \ell(v) + 1$  for all edges (u, v) in the residual graph  $G_f$  (only non-zero capacity edges!!!)
- $\ell(s) = n$
- ▶  $\ell(t) = 0$

### Intuition:

The labelling can be viewed as a height function. Whenever the height from node u to node v decreases by more than 1 (i.e., it goes very steep downhill from u to v), the corresponding edge must be saturated.

13.1 Generic Push Relabel

11. Apr. 2018 450/550

## Lemma 69

A preflow that has a valid labelling saturates a cut.

Proof:

- There are n nodes but n + 1 different labels from  $0, \ldots, n$ .
- ► There must exist a label d ∈ {0,..., n} such that none of the nodes carries this label.
- Let  $A = \{v \in V \mid \ell(v) > d\}$  and  $B = \{v \in V \mid \ell(v) < d\}$ .
- We have s ∈ A and t ∈ B and there is no edge from A to B in the residual graph G<sub>f</sub>; this means that (A, B) is a saturated cut.

### Lemma 70

A flow that has a valid labelling is a maximum flow.

# **Push Relabel Algorithms**

### Idea:

- start with some preflow and some valid labelling
- successively change the preflow while maintaining a valid labelling
- stop when you have a flow (i.e., no more active nodes)

Note that this is somewhat dual to an augmenting path algorithm. The former maintains the property that it has a feasible flow. It successively changes this flow until it saturates some cut in which case we conclude that the flow is maximum. A preflow push algorithm maintains the property that it has a saturated cut. The preflow is changed iteratively until it fulfills conservation constraints in which case we can conclude that we have a maximum flow.

# **Changing a Preflow**

An arc (u, v) with  $c_f(u, v) > 0$  in the residual graph is admissible if  $\ell(u) = \ell(v) + 1$  (i.e., it goes downwards w.r.t. labelling  $\ell$ ).

## The push operation

Consider an active node u with excess flow  $f(u) = \sum_{e \in into(u)} f(e) - \sum_{e \in out(u)} f(e)$  and suppose e = (u, v)is an admissible arc with residual capacity  $c_f(e)$ .

We can send flow  $\min\{c_f(e), f(u)\}$  along e and obtain a new preflow. The old labelling is still valid (!!!).

saturating and non-saturating at

the same time.

- saturating push: min{f(u), c<sub>f</sub>(e)} = c<sub>f</sub>(e) the arc e is deleted from the residual graph
- non-saturating push: min{f(u), c<sub>f</sub>(e)} = f(u) the node u becomes inactive
  Note that a push-operation may be;

# **Push Relabel Algorithms**

### The relabel operation

Consider an active node u that does not have an outgoing admissible arc.

Increasing the label of u by 1 results in a valid labelling.

- Edges (w, u) incoming to u still fulfill their constraint  $\ell(w) \le \ell(u) + 1$ .
- An outgoing edge (u, w) had ℓ(u) < ℓ(w) + 1 before since it was not admissible. Now: ℓ(u) ≤ ℓ(w) + 1.

# **Push Relabel Algorithms**

### Intuition:

We want to send flow downwards, since the source has a height/label of n and the target a height/label of 0. If we see an active node u with an admissible arc we push the flow at u towards the other end-point that has a lower height/label. If we do not have an admissible arc but excess flow into u it should roughly mean that the level/height/label of u should rise. (If we consider the flow to be water then this would be natural.)

Note that the above intuition is very incorrect as the labels are integral, i.e., they cannot really be seen as the height of a node.

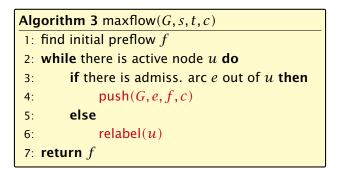

# Reminder

- In a preflow nodes may not fulfill conservation constraints; a node may have more incoming flow than outgoing flow.
- Such a node is called active.
- A labelling is valid if for every edge (u, v) in the residual graph  $\ell(u) \le \ell(v) + 1$ .
- An arc (u, v) in residual graph is admissible if  $\ell(u) = \ell(v) + 1$ .
- A saturating push along *e* pushes an amount of *c*(*e*) flow along the edge, thereby saturating the edge (and making it dissappear from the residual graph).
- A non-saturating push along e = (u, v) pushes a flow of f(u), where f(u) is the excess flow of u. This makes u inactive.

# **Push Relabel Algorithms**

In the following example we always stick to the same active node u until it becomes inactive but this is not required.

## **Preflow Push Algorithm**

Animation for push relabel algorithms is only available in the lecture version of the slides.

13.1 Generic Push Relabel

11. Apr. 2018 458/550

# Analysis

Note that the lemma is almost trivial. A node v having excess flow means that the current preflow ships something to v. The residual graph allows to *undo* flow. Therefore, there must exist a path that can undo the shipment and move it back to *s*. However, a formal proof is required.

### Lemma 71

An active node has a path to *s* in the residual graph.

## Proof.

- ► Let A denote the set of nodes that can reach s, and let B denote the remaining nodes. Note that s ∈ A.
- ▶ In the following we show that a node  $b \in B$  has excess flow f(b) = 0 which gives the lemma.
- In the residual graph there are no edges into A, and, hence, no edges leaving A/entering B can carry any flow.
- Let  $f(B) = \sum_{v \in B} f(v)$  be the excess flow of all nodes in *B*.

Let  $f : E \to \mathbb{R}^+_0$  be a preflow. We introduce the notation

$$f(x,y) = \begin{cases} 0 & (x,y) \notin E \\ f((x,y)) & (x,y) \in E \end{cases}$$

#### We have

$$\begin{split} f(B) &= \sum_{b \in B} f(b) \\ &= \sum_{b \in B} \left( \sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right) \\ &= \sum_{b \in B} \left( \sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right) \\ &= -\sum_{b \in B} \sum_{v \in A} f(b, v) \\ &\leq 0 \end{split}$$

Hence, the excess flow f(b) must be 0 for every node  $b \in B$ .

	Ernst Mayr,	Harald	Räcke

13.1 Generic Push Relabel

# Analysis

#### Lemma 72

The label of a node cannot become larger than 2n - 1.

### Proof.

▶ When increasing the label at a node *u* there exists a path from *u* to *s* of length at most *n* − 1. Along each edge of the path the height/label can at most drop by 1, and the label of the source is *n*.

#### Lemma 73

There are only  $\mathcal{O}(n^2)$  relabel operations.

### Lemma 74

The number of saturating pushes performed is at most O(mn).

### Proof.

- Suppose that we just made a saturating push along (u, v).
- Hence, the edge (u, v) is deleted from the residual graph.
- For the edge to appear again, a push from v to u is required.
- Currently,  $\ell(u) = \ell(v) + 1$ , as we only make pushes along admissible edges.
- For a push from v to u the edge (v, u) must become admissible. The label of v must increase by at least 2.
- Since the label of v is at most 2n − 1, there are at most n pushes along (u, v).

### Lemma 75

The number of non-saturating pushes performed is at most  $O(n^2m)$ .

### Proof.

- Define a potential function  $\Phi(f) = \sum_{\text{active nodes}v} \ell(v)$
- A saturating push increases Φ by ≤ 2n (when the target node becomes active it may contribute at most 2n to the sum).
- A relabel increases  $\Phi$  by at most 1.
- ► A non-saturating push decreases Φ by at least 1 as the node that is pushed from becomes inactive and has a label that is strictly larger than the target.
- Hence,

#non-saturating\_pushes  $\leq$  #relabels +  $2n \cdot$  #saturating\_pushes  $\leq O(n^2m)$ .

#### **Theorem 76**

# There is an implementation of the generic push relabel algorithm with running time $O(n^2m)$ .

13.1 Generic Push Relabel

11. Apr. 2018 464/550

Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge (u, v) can be performed in constant time

- check whether edge (v, u) needs to be added to G<sub>f</sub>
- check whether (u, v) needs to be deleted (saturating push)
- check whether u becomes inactive and has to be deleted from the set of active nodes

A relabel at a node u can be performed in time  $\mathcal{O}(n)$ 

- check for all outgoing edges if they become admissible
- check for all incoming edges if they become non-admissible

For special variants of push relabel algorithms we organize the neighbours of a node into a linked list (possible neighbours in the residual graph  $G_f$ ). Then we use the discharge-operation:

Algorithm 4 discharge( <i>u</i> )
1: <b>while</b> <i>u</i> is active <b>do</b>
2: $v \leftarrow u.current-neighbour$
3: <b>if</b> $v$ = null <b>then</b>
4: relabel(u)
5: $u.current-neighbour \leftarrow u.neighbour-list-head$
6: else
7: <b>if</b> $(u, v)$ admissible <b>then</b> push $(u, v)$
8: <b>else</b> <i>u.current-neighbour</i> $\leftarrow$ <i>v.next-in-list</i>

Note that *u.current-neighbour* is a global variable. It is only changed within the discharge routine, but keeps its value between consecutive calls to discharge.

### Lemma 77

If v = null in Line 3, then there is no outgoing admissible edge from u.

### Proof.

In order for e to become admissible the other end-point say v has to push flow to u (so that the edge (u, v) re-appears in the residual graph). For this the label of v needs to be larger than the label of u. Then in order to make (u, v) admissible the label of u has to increase.

- While pushing from u the current-neighbour pointer is only advanced if the current edge is not admissible.
- The only thing that could make the edge admissible again would be a relabel at u.
- If we reach the end of the list (v = null) all edges are not admissible.

This shows that discharge(u) is correct, and that we can perform a relabel in Line 4.

# 13.2 Relabel to Front

```
Algorithm 21 relabel-to-front(G, s, t)
1: initialize preflow
2: initialize node list L containing V \setminus \{s, t\} in any order
3: foreach u \in V \setminus \{s, t\} do
        u.current-neighbour \leftarrow u.neighbour-list-head
4.
5: u \leftarrow L head
6: while \mu \neq null do
         old-height \leftarrow \ell(u)
7:
8:
         discharge(u)
         if \ell(u) > old-height then // relabel happened
9:
               move u to the front of L
10:
11:
         u \leftarrow u.next
```

# 13.2 Relabel to Front

### Lemma 78 (Invariant)

*In Line 6 of the relabel-to-front algorithm the following invariant holds.* 

- 1. The sequence L is topologically sorted w.r.t. the set of admissible edges; this means for an admissible edge (x, y) the node x appears before y in sequence L.
- **2.** No node before u in the list L is active.

### **Proof:**

- Initialization:
  - 1. In the beginning *s* has label  $n \ge 2$ , and all other nodes have label 0. Hence, no edge is admissible, which means that any ordering *L* is permitted.
  - 2. We start with *u* being the head of the list; hence no node before *u* can be active
- Maintenance:
  - Pushes do no create any new admissible edges. Therefore, if discharge() does not relabel u, L is still topologically sorted.
    - After relabeling, *u* cannot have admissible incoming edges as such an edge (x, u) would have had a difference  $\ell(x) \ell(u) \ge 2$  before the re-labeling (such edges do not exist in the residual graph).

Hence, moving u to the front does not violate the sorting property for any edge; however it fixes this property for all admissible edges leaving u that were generated by the relabeling.

# 13.2 Relabel to Front

### Proof:

- Maintenance:
  - If we do a relabel there is nothing to prove because the only node before u' (u in the next iteration) will be the current u; the discharge(u) operation only terminates when u is not active anymore.

For the case that we do not relabel, observe that the only way a predecessor could be active is that we push flow to it via an admissible arc. However, all admissible arc point to successors of u.

Note that the invariant means that for u = null we have a preflow with a valid labelling that does not have active nodes. This means we have a maximum flow.

# 13.2 Relabel to Front

#### Lemma 79

There are at most  $\mathcal{O}(n^3)$  calls to discharge(u).

Every discharge operation without a relabel advances u (the current node within list L). Hence, if we have n discharge operations without a relabel we have u = null and the algorithm terminates.

Therefore, the number of calls to discharge is at most  $n(\#relabels + 1) = O(n^3)$ .

13.2 Relabel to Front

### Lemma 80

The cost for all relabel-operations is only  $\mathcal{O}(n^2)$ .

A relabel-operation at a node is constant time (increasing the label and resetting *u.current-neighbour*). In total we have  $O(n^2)$  relabel-operations.

13.2 Relabel to Front

# 13.2 Relabel to Front

Note that by definition a saturating push operation  $(\min\{c_f(e), f(u)\} = c_f(e))$  can at the same time be a non-saturating push operation  $(\min\{c_f(e), f(u)\} = f(u))$ .

### Lemma 81

The cost for all saturating push-operations that are **not** also non-saturating push-operations is only O(mn).

Note that such a push-operation leaves the node u active but makes the edge e disappear from the residual graph. Therefore the push-operation is immediately followed by an increase of the pointer u.current-neighbour.

This pointer can traverse the neighbour-list at most O(n) times (upper bound on number of relabels) and the neighbour-list has only degree(u) + 1 many entries (+1 for null-entry).

# 13.2 Relabel to Front

#### Lemma 82

The cost for all non-saturating push-operations is only  $\mathcal{O}(n^3)$ .

A non-saturating push-operation takes constant time and ends the current call to discharge(). Hence, there are only  $\mathcal{O}(n^3)$  such operations.

#### Theorem 83

The push-relabel algorithm with the rule relabel-to-front takes time  $\mathcal{O}(n^3)$ .

### **Algorithm 6** highest-label(*G*, *s*, *t*)

1: initialize preflow

2: foreach 
$$u \in V \setminus \{s, t\}$$
 do

3: *u.current-neighbour* ← *u.neighbour-list-head* 

### 4: while $\exists$ active node u do

5: select active node *u* with highest label

6: discharge(u)

#### Lemma 84

When using highest label the number of non-saturating pushes is only  $\mathcal{O}(n^3)$ .

A push from a node on level  $\ell$  can only "activate" nodes on levels strictly less than  $\ell.$ 

This means, after a non-saturating push from u a relabel is required to make u active again.

Hence, after n non-saturating pushes without an intermediate relabel there are no active nodes left.

Therefore, the number of non-saturating pushes is at most  $n(\#relabels + 1) = O(n^3)$ .

Since a discharge-operation is terminated by a non-saturating push this gives an upper bound of  $\mathcal{O}(n^3)$  on the number of discharge-operations.

The cost for relabels and saturating pushes can be estimated in exactly the same way as in the case of the generic push-relabel algorithm.

#### Question:

How do we find the next node for a discharge operation?

Maintain lists  $L_i$ ,  $i \in \{0, ..., 2n\}$ , where list  $L_i$  contains active nodes with label i (maintaining these lists induces only constant additional cost for every push-operation and for every relabel-operation).

After a discharge operation terminated for a node u with label k, traverse the lists  $L_k, L_{k-1}, \ldots, L_0$ , (in that order) until you find a non-empty list.

Unless the last (non-saturating) push was to s or t the list k - 1 must be non-empty (i.e., the search takes constant time).

Hence, the total time required for searching for active nodes is at most

 $\mathcal{O}(n^3) + n(\#non-saturating-pushes-to-s-or-t)$ 

#### Lemma 85

The number of non-saturating pushes to s or t is at most  $O(n^2)$ .

With this lemma we get

**Theorem 86** The push-relabel algorithm with the rule highest-label takes time  $\mathcal{O}(n^3)$ .

13.3 Highest Label

### Proof of the Lemma.

- ► We only show that the number of pushes to the source is at most O(n<sup>2</sup>). A similar argument holds for the target.
- After a node v (which must have ℓ(v) = n + 1) made a non-saturating push to the source there needs to be another node whose label is increased from ≤ n + 1 to n + 2 before v can become active again.
- This happens for every push that v makes to the source. Since, every node can pass the threshold n + 2 at most once, v can make at most n pushes to the source.
- As this holds for every node the total number of pushes to the source is at most  $O(n^2)$ .

### **Mincost Flow**

### **Problem Definition:**

min  $\sum_{e} c(e) f(e)$ s.t.  $\forall e \in E: 0 \le f(e) \le u(e)$  $\forall v \in V: f(v) = b(v)$ 

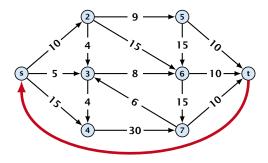

- G = (V, E) is a directed graph.
- $u: E \to \mathbb{R}^+_0 \cup \{\infty\}$  is the capacity function.
- $c: E \to \mathbb{R}$  is the cost function (note that c(e) may be negative).
- ▶  $b: V \to \mathbb{R}$ ,  $\sum_{v \in V} b(v) = 0$  is a demand function.

14 Mincost Flow

11. Apr. 2018 482/550

# Solve Maxflow Using Mincost Flow

- Given a flow network for a standard maxflow problem.
- Set b(v) = 0 for every node. Keep the capacity function u for all edges. Set the cost c(e) for every edge to 0.
- Add an edge from t to s with infinite capacity and cost -1.
- Then,  $val(f^*) = -cost(f_{min})$ , where  $f^*$  is a maxflow, and  $f_{min}$  is a mincost-flow.

14 Mincost Flow

# Solve Maxflow Using Mincost Flow

### Solve decision version of maxflow:

- Given a flow network for a standard maxflow problem, and a value k.
- Set b(v) = 0 for every node apart from s or t. Set b(s) = −k and b(t) = k.
- Set edge-costs to zero, and keep the capacities.
- There exists a maxflow of value at least k if and only if the mincost-flow problem is feasible.

### Generalization

Our model:

$$\begin{array}{ll} \min & \sum_{e} c(e) f(e) \\ \text{s.t.} & \forall e \in E : \ 0 \le f(e) \le u(e) \\ & \forall v \in V : \ f(v) = b(v) \end{array}$$

where  $b: V \to \mathbb{R}$ ,  $\sum_{v} b(v) = 0$ ;  $u: E \to \mathbb{R}^+_0 \cup \{\infty\}$ ;  $c: E \to \mathbb{R}$ ;

### A more general model?

min 
$$\sum_{e} c(e) f(e)$$
  
s.t.  $\forall e \in E : \ell(e) \le f(e) \le u(e)$   
 $\forall v \in V : a(v) \le f(v) \le b(v)$ 

where  $a: V \to \mathbb{R}, b: V \to \mathbb{R}; \ell: E \to \mathbb{R} \cup \{-\infty\}, u: E \to \mathbb{R} \cup \{\infty\}$  $c: E \to \mathbb{R};$ 

## Generalization

### Differences

- Flow along an edge e may have non-zero lower bound  $\ell(e)$ .
- Flow along e may have negative upper bound u(e).
- The demand at a node v may have lower bound a(v) and upper bound b(v) instead of just lower bound = upper bound = b(v).

14 Mincost Flow

# **Reduction I**

$$\begin{array}{ll} \min & \sum_{e} c(e) f(e) \\ \text{s.t.} & \forall e \in E : \ \ell(e) \le f(e) \le u(e) \\ & \forall v \in V : \ a(v) \le f(v) \le b(v) \end{array}$$

### We can assume that a(v) = b(v):

Add new node r.

Add edge (r, v) for all  $v \in V$ .

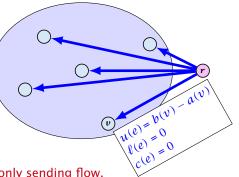

Set  $\ell(e) = c(e) = 0$  for these edges.

Set u(e) = b(v) - a(v) for edge (r, v).

Set a(v) = b(v) for all  $v \in V$ .

Set  $b(r) = -\sum_{v \in V} b(v)$ .

 $-\sum_{v} b(v)$  is negative; hence r is only sending flow.

## **Reduction II**

min 
$$\sum_{e} c(e) f(e)$$
  
s.t.  $\forall e \in E : \ell(e) \le f(e) \le u(e)$   
 $\forall v \in V : f(v) = b(v)$ 

We can assume that either  $\ell(e) \neq -\infty$  or  $u(e) \neq \infty$ :

If c(e) = 0 we can contract the edge/identify nodes u and v.

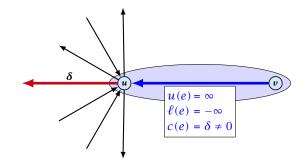

If  $c(e) \neq 0$  we can transform the graph so that c(e) = 0.

14 Mincost Flow

# **Reduction II**

We can transform any network so that a particular edge has cost c(e) = 0:

Additionally we set b(u) = 0.

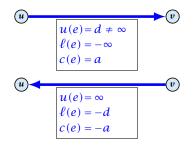

14 Mincost Flow

11. Apr. 2018 489/550

# **Reduction III**

$$\begin{array}{ll} \min & \sum_{e} c(e) f(e) \\ \text{s.t.} & \forall e \in E : \ \ell(e) \leq f(e) \leq u(e) \\ & \forall v \in V : \ f(v) = b(v) \end{array}$$

We can assume that  $\ell(e) \neq -\infty$ :

Replace the edge by an edge in opposite direction.

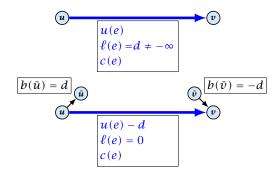

14 Mincost Flow

11. Apr. 2018 490/550

# **Reduction IV**

min 
$$\sum_{e} c(e) f(e)$$
  
s.t.  $\forall e \in E : \ell(e) \le f(e) \le u(e)$   
 $\forall v \in V : f(v) = b(v)$ 

We can assume that  $\ell(e) = 0$ :

The added edges have infinite capacity and cost c(e)/2.

14 Mincost Flow

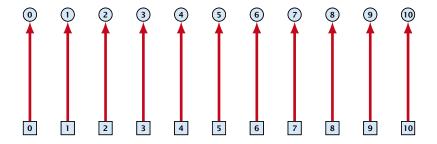

11. Apr. 2018 491/550

# **Applications**

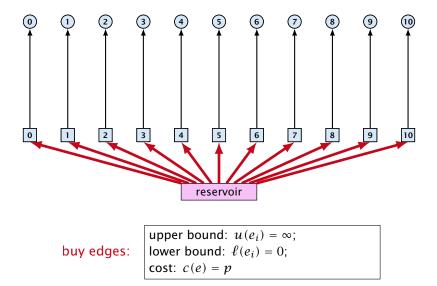

### **Caterer Problem**

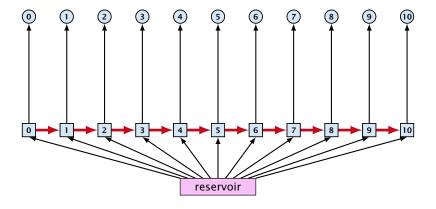

- She needs to supply  $r_i$  napkins on N successive days.
- She can buy new napkins at *p* cents each.
- She can launder them at a fast laundry that takes m days and cost f cents a napkin.
- She can use a slow laundry that takes k > m days and costs s cents each.
- At the end of each day she should determine how many to send to each laundry and how many to buy in order to fulfill demand.
- Minimize cost.

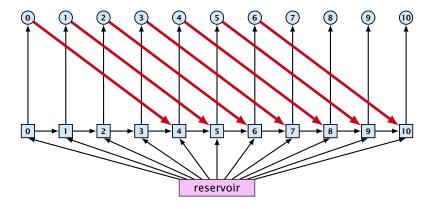

day edges: upper bound:  $u(e_i) = \infty$ ; lower bound:  $\ell(e_i) = r_i$ ; cost: c(e) = 0

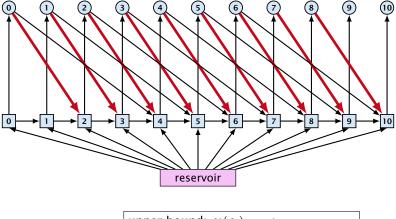

forward edges:

upper bound:  $u(e_i) = \infty$ ; lower bound:  $\ell(e_i) = 0$ ; cost: c(e) = 0

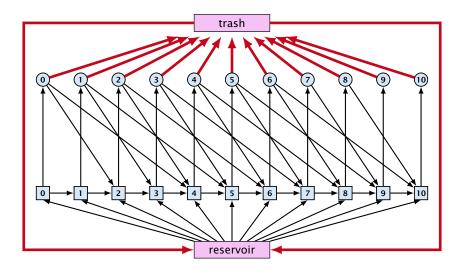

slow edges:

upper bound:  $u(e_i) = \infty$ ; lower bound:  $\ell(e_i) = 0$ ; cost: c(e) = s

fast edges:

upper bound:  $u(e_i) = \infty$ ; lower bound:  $\ell(e_i) = 0$ ; cost: c(e) = f

trash edges:

upper bound:  $u(e_i) = \infty$ ; lower bound:  $\ell(e_i) = 0$ ; cost: c(e) = 0

### **Residual Graph**

#### Version A:

The residual graph G' for a mincost flow is just a copy of the graph G.

If we send f(e) along an edge, the corresponding edge e' in the residual graph has its lower and upper bound changed to  $\ell(e') = \ell(e) - f(e)$  and u(e') = u(e) - f(e).

#### Version B:

The residual graph for a mincost flow is exactly defined as the residual graph for standard flows, with the only exception that one needs to define a cost for the residual edge.

For a flow of z from u to v the residual edge (v, u) has capacity z and a cost of -c((u, v)).

14 Mincost Flow

A circulation in a graph G = (V, E) is a function  $f : E \to \mathbb{R}^+$  that has an excess flow f(v) = 0 for every node  $v \in V$ .

A circulation is feasible if it fulfills capacity constraints, i.e.,  $f(e) \le u(e)$  for every edge of *G*.

14 Mincost Flow

#### Lemma 87

A given flow is a mincost-flow if and only if the corresponding residual graph  $G_f$  does not have a feasible circulation of negative cost.

⇒ Suppose that g is a feasible circulation of negative cost in the residual graph.

Then f + g is a feasible flow with cost cost(f) + cost(g) < cost(f). Hence, f is not minimum cost.

⇐ Let f be a non-mincost flow, and let f\* be a min-cost flow.
 We need to show that the residual graph has a feasible circulation with negative cost.

Clearly  $f^* - f$  is a circulation of negative cost. One can also easily see that it is feasible for the residual graph. (after sending -f in the residual graph (pushing all flow back) we arrive at the original graph; for this  $f^*$  is clearly feasible)

# For previous slide: $g = f^* - f$ is obtained by computing $\Delta(e) = f^*(e) - f(e)$ for every edge e = (u, v). If the result is positive set $g((u, v)) = \Delta(e)$ and g((v, u)) = 0. Otherwise set g((u, v)) = 0 and $g((v, u)) = -\Delta(e)$ .

14 Mincost Flow

#### Lemma 88

A graph (without zero-capacity edges) has a feasible circulation of negative cost if and only if it has a negative cycle w.r.t. edge-weights  $c : E \to \mathbb{R}$ .

#### Proof.

- Suppose that we have a negative cost circulation.
- Find directed cycle only using edges that have non-zero flow.
- If this cycle has negative cost you are done.
- Otherwise send flow in opposite direction along the cycle until the bottleneck edge(s) does not carry any flow.
- You still have a circulation with negative cost.
- Repeat.

**Algorithm 23** CycleCanceling(G = (V, E), c, u, b)

- 1: establish a feasible flow f in G
- 2: while  $G_f$  contains negative cycle do
- 3: use Bellman-Ford to find a negative circuit Z

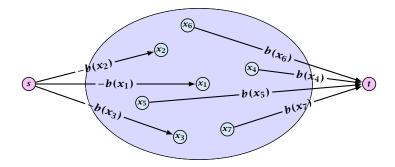

4: 
$$\delta \leftarrow \min\{u_f(e) \mid e \in Z\}$$

5: augment  $\delta$  units along Z and update  $G_f$ 

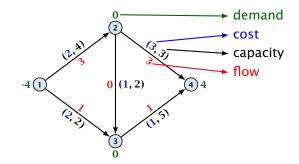

14 Mincost Flow

#### How do we find the initial feasible flow?

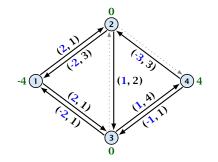

- Connect new node s to all nodes with negative b(v)-value.
- Connect nodes with positive b(v)-value to a new node t.
- There exist a feasible flow in the original graph iff in the resulting graph there exists an *s*-*t* flow of value

$$\sum_{\nu:b(\nu)<0} (-b(\nu)) = \sum_{\nu:b(\nu)>0} b(\nu) \; .$$

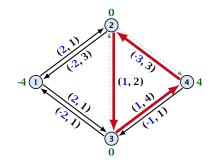

14 Mincost Flow

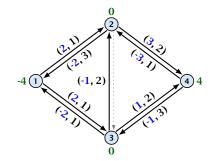

14 Mincost Flow

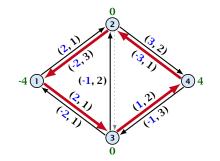

14 Mincost Flow

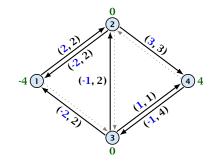

14 Mincost Flow

14 Mincost Flow

14 Mincost Flow

#### Lemma 89

The improving cycle algorithm runs in time  $O(nm^2CU)$ , for integer capacities and costs, when for all edges e,  $|c(e)| \le C$  and  $|u(e)| \le U$ .

- Running time of Bellman-Ford is  $\mathcal{O}(mn)$ .
- Pushing flow along the cycle can be done in time  $\mathcal{O}(n)$ .
- Each iteration decreases the total cost by at least 1.
- The true optimum cost must lie in the interval [-mCU, ..., +mCU].

Note that this lemma is weak since it does not allow for edges with infinite capacity.

A general mincost flow problem is of the following form:

min 
$$\sum_{e} c(e) f(e)$$
  
s.t.  $\forall e \in E : \ell(e) \le f(e) \le u(e)$   
 $\forall v \in V : a(v) \le f(v) \le b(v)$ 

where  $a: V \to \mathbb{R}$ ,  $b: V \to \mathbb{R}$ ;  $\ell: E \to \mathbb{R} \cup \{-\infty\}$ ,  $u: E \to \mathbb{R} \cup \{\infty\}$  $c: E \to \mathbb{R}$ ;

#### Lemma 90 (without proof)

A general mincost flow problem can be solved in polynomial time.

14 Mincost Flow

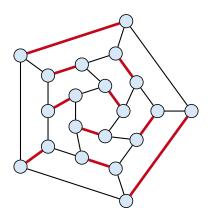

# Part V

## Matchings

### Matching

- Input: undirected graph G = (V, E).
- $M \subseteq E$  is a matching if each node appears in at most one edge in M.
- Maximum Matching: find a matching of maximum cardinality

### **16 Bipartite Matching via Flows**

#### Which flow algorithm to use?

- Generic augmenting path:  $\mathcal{O}(m \operatorname{val}(f^*)) = \mathcal{O}(mn)$ .
- Capacity scaling:  $\mathcal{O}(m^2 \log C) = \mathcal{O}(m^2)$ .
- Shortest augmenting path:  $\mathcal{O}(mn^2)$ .

For unit capacity simple graphs shortest augmenting path can be implemented in time  $\mathcal{O}(m\sqrt{n})$ .

#### Definitions.

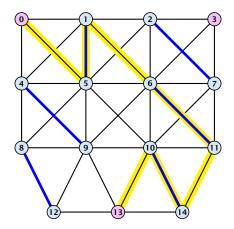

- Given a matching M in a graph G, a vertex that is not incident to any edge of M is called a free vertex w.r.t. M.
- ▶ For a matching *M* a path *P* in *G* is called an alternating path if edges in *M* alternate with edges not in *M*.
- An alternating path is called an augmenting path for matching *M* if it ends at distinct free vertices.

#### Theorem 91

A matching M is a maximum matching if and only if there is no augmenting path w. r. t. M.

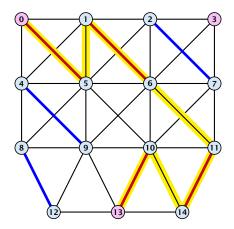

### **Augmenting Paths in Action**

17 Augmenting Paths for Matchings

### **Augmenting Paths in Action**

17 Augmenting Paths for Matchings

Proof.

- ⇒ If *M* is maximum there is no augmenting path *P*, because we could switch matching and non-matching edges along *P*. This gives matching  $M' = M \oplus P$  with larger cardinality.
- $\leftarrow Suppose there is a matching M' with larger cardinality. Consider the graph H with edge-set M' \oplus M (i.e., only edges that are in either M or M' but not in both).$

Each vertex can be incident to at most two edges (one from M and one from M'). Hence, the connected components are alternating cycles or alternating path.

As |M'| > |M| there is one connected component that is a path P for which both endpoints are incident to edges from M'. P is an alternating path.

#### Algorithmic idea:

As long as you find an augmenting path augment your matching using this path. When you arrive at a matching for which no augmenting path exists you have a maximum matching.

#### Theorem 92

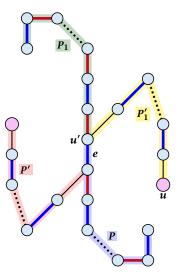

Let G be a graph, M a matching in G, and let u be a free vertex w.r.t. M. Further let P denote an augmenting path w.r.t. M and let  $M' = M \oplus P$  denote the matching resulting from augmenting M with P. If there was no augmenting path starting at u in M then there is no augmenting path starting at u in M'.

The above theorem allows for an easier implementation of an augmenting path algorithm. Once we checked for augmenting paths starting from u we don't have to check for such paths in future rounds.

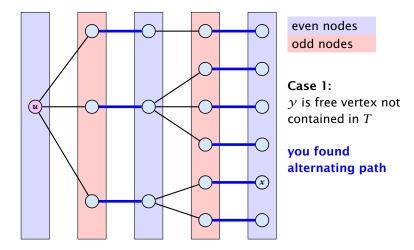

#### Proof

- Assume there is an augmenting path P' w.r.t. M' starting at u.
- If P' and P are node-disjoint, P' is also augmenting path w.r.t. M (£).
- Let u' be the first node on P' that is in P, and let e be the matching edge from M' incident to u'.
- u' splits P into two parts one of which does not contain e. Call this part P<sub>1</sub>. Denote the sub-path of P' from u to u' with P'<sub>1</sub>.
- $P_1 \circ P'_1$  is augmenting path in M (4).

Construct an alternating tree.

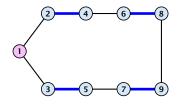

18 Maximum Matching in General Graphs

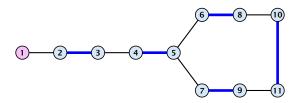

#### **Definition 93**

A flower in a graph G = (V, E) w.r.t. a matching M and a (free) root node r, is a subgraph with two components:

- A stem is an even length alternating path that starts at the root node r and terminates at some node w. We permit the possibility that r = w (empty stem).
- A blossom is an odd length alternating cycle that starts and terminates at the terminal node w of a stem and has no other node in common with the stem. w is called the base of the blossom.

18 Maximum Matching in General Graphs

#### **Properties:**

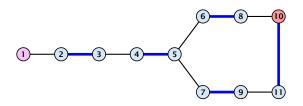

- 1. A stem spans  $2\ell + 1$  nodes and contains  $\ell$  matched edges for some integer  $\ell \ge 0$ .
- **2.** A blossom spans 2k + 1 nodes and contains k matched edges for some integer  $k \ge 1$ . The matched edges match all nodes of the blossom except the base.
- **3.** The base of a blossom is an even node (if the stem is part of an alternating tree starting at *r*).

#### **Properties:**

- 4. Every node x in the blossom (except its base) is reachable from the root (or from the base of the blossom) through two distinct alternating paths; one with even and one with odd length.
- 5. The even alternating path to x terminates with a matched edge and the odd path with an unmatched edge.

18 Maximum Matching in General Graphs

11. Apr. 2018 522/550

## **Shrinking Blossoms**

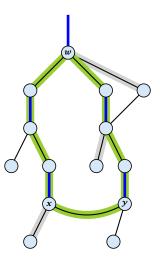

When during the alternating tree construction we discover a blossom B we replace the graph G by G' = G/B, which is obtained from G by contracting the blossom B.

- Delete all vertices in B (and its incident edges) from G.
- Add a new (pseudo-)vertex b. The new vertex b is connected to all vertices in V \ B that had at least one edge to a vertex from B.

# **Shrinking Blossoms**

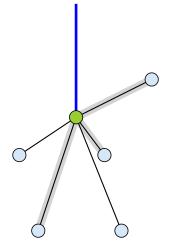

- Edges of T that connect a node u not in B to a node in B become tree edges in T' connecting u to b.
- Matching edges (there is at most one) that connect a node u not in B to a node in B become matching edges in M'.
- Nodes that are connected in G to at least one node in B become connected to b in G'.

# **Shrinking Blossoms**

- Edges of T that connect a node u not in B to a node in B become tree edges in T' connecting u to b.
- Matching edges (there is at most one) that connect a node u not in B to a node in B become matching edges in M'.
- Nodes that are connected in G to at least one node in B become connected to b in G'.

## **Example: Blossom Algorithm**

Animation of Blossom Shrinking algorithm is only available in the lecture version of the slides.

18 Maximum Matching in General Graphs

11. Apr. 2018 525/550

Assume that in *G* we have a flower w.r.t. matching *M*. Let *r* be the root, *B* the blossom, and *w* the base. Let graph G' = G/B with pseudonode *b*. Let *M'* be the matching in the contracted graph.

#### Lemma 94

If G' contains an augmenting path P' starting at r (or the pseudo-node containing r) w.r.t. the matching M' then G contains an augmenting path starting at r w.r.t. matching M.

18 Maximum Matching in General Graphs

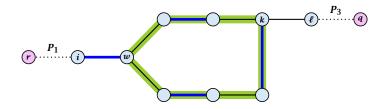

Proof.

If P' does not contain b it is also an augmenting path in G.

#### Case 1: non-empty stem

Next suppose that the stem is non-empty.

18 Maximum Matching in General Graphs

11. Apr. 2018 527/550

- ► After the expansion ℓ must be incident to some node in the blossom. Let this node be k.
- If  $k \neq w$  there is an alternating path  $P_2$  from w to k that ends in a matching edge.
- ▶  $P_1 \circ (i, w) \circ P_2 \circ (k, \ell) \circ P_3$  is an alternating path.
- ▶ If k = w then  $P_1 \circ (i, w) \circ (w, \ell) \circ P_3$  is an alternating path.

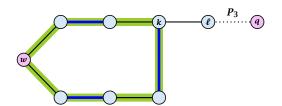

### Proof.

#### Case 2: empty stem

If the stem is empty then after expanding the blossom,

w = r.

• The path  $r \circ P_2 \circ (k, \ell) \circ P_3$  is an alternating path.

#### Lemma 95

If G contains an augmenting path P from r to q w.r.t. matching M then G' contains an augmenting path from r (or the pseudo-node containing r) to q w.r.t. M'.

18 Maximum Matching in General Graphs

11. Apr. 2018 530/550

#### Proof.

- If P does not contain a node from B there is nothing to prove.
- We can assume that *r* and *q* are the only free nodes in *G*.

#### Case 1: empty stem

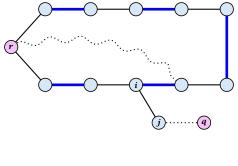

Let i be the last node on the path P that is part of the blossom.

P is of the form  $P_1 \circ (i, j) \circ P_2$ , for some node j and (i, j) is unmatched.

 $(b, j) \circ P_2$  is an augmenting path in the contracted network.

Illustration for Case 1:

18 Maximum Matching in General Graphs

11. Apr. 2018 532/550

#### Case 2: non-empty stem

Let  $P_3$  be alternating path from r to w; this exists because r and w are root and base of a blossom. Define  $M_+ = M \oplus P_3$ .

In  $M_+$ , r is matched and w is unmatched.

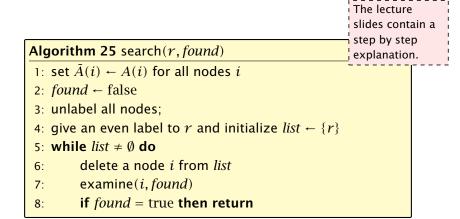

*G* must contain an augmenting path w.r.t. matching  $M_+$ , since *M* and  $M_+$  have same cardinality.

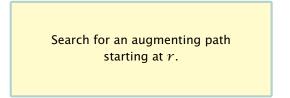

This path must go between w and q as these are the only unmatched vertices w.r.t.  $M_+$ .

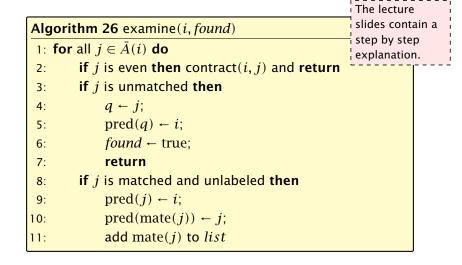

For  $M'_+$  the blossom has an empty stem. Case 1 applies.

G' has an augmenting path w.r.t.  $M'_+$ . It must also have an augmenting path w.r.t. M', as both matchings have the same cardinality.

This path must go between r and q.

Examine the neighbours of a node *i* 

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

Contract blossom identified by nodes i and j

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

Get all nodes of the blossom.

Time:  $\mathcal{O}(m)$ 

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node *b* and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

Identify all neighbours of *b*.

Time:  $\mathcal{O}(m)$  (how?)

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

*b* will be an even node, and it has unexamined neighbours.

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

Every node that was adjacent to a node in *B* is now adjacent to *b* 

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B
- 6: delete nodes in *B* from the graph

Only for making a blossom expansion easier.

- 1: trace pred-indices of i and j to identify a blossom B
- 2: create new node b and set  $\bar{A}(b) \leftarrow \bigcup_{x \in B} \bar{A}(x)$
- 3: label *b* even and add to *list*
- 4: update  $\bar{A}(j) \leftarrow \bar{A}(j) \cup \{b\}$  for each  $j \in \bar{A}(b)$
- 5: form a circular double linked list of nodes in B

6: delete nodes in *B* from the graph

Only delete links from nodes not in *B* to *B*.

When expanding the blossom again we can recreate these links in time  $\mathcal{O}(m)$ .

# Analysis

- A contraction operation can be performed in time O(m).
   Note, that any graph created will have at most m edges.
- The time between two contraction-operation is basically a BFS/DFS on a graph. Hence takes time O(m).
- There are at most n contractions as each contraction reduces the number of vertices.
- The expansion can trivially be done in the same time as needed for all contractions.
- An augmentation requires time O(n). There are at most n of them.
- In total the running time is at most

$$n \cdot (\mathcal{O}(mn) + \mathcal{O}(n)) = \mathcal{O}(mn^2)$$
.

## **Example: Blossom Algorithm**

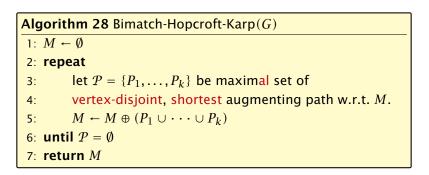

Animation of Blossom Shrinking algorithm is only available in the lecture version of the slides.

18 Maximum Matching in General Graphs

11. Apr. 2018 538/550

# A Fast Matching Algorithm

We call one iteration of the repeat-loop a phase of the algorithm.

### Lemma 96

Given a matching M and a maximal matching  $M^*$  there exist  $|M^*| - |M|$  vertex-disjoint augmenting path w.r.t. M.

### Proof:

- Similar to the proof that a matching is optimal iff it does not contain an augmenting path.
- Consider the graph G = (V, M ⊕ M\*), and mark edges in this graph blue if they are in M and red if they are in M\*.
- The connected components of *G* are cycles and paths.
- ► The graph contains k ≝ |M\*| |M| more red edges than blue edges.
- Hence, there are at least k components that form a path starting and ending with a red edge. These are augmenting paths w.r.t. M.

- Let  $P_1, \ldots, P_k$  be a maximal collection of vertex-disjoint, shortest augmenting paths w.r.t. *M* (let  $\ell = |P_i|$ ).
- $M' \stackrel{\text{\tiny def}}{=} M \oplus (P_1 \cup \cdots \cup P_k) = M \oplus P_1 \oplus \cdots \oplus P_k.$
- Let P be an augmenting path in M'.

#### Lemma 97

The set  $A \cong M \oplus (M' \oplus P) = (P_1 \cup \cdots \cup P_k) \oplus P$  contains at least  $(k+1)\ell$  edges.

### Proof.

- The set describes exactly the symmetric difference between matchings M and  $M' \oplus P$ .
- ► Hence, the set contains at least k + 1 vertex-disjoint augmenting paths w.r.t. M as |M'| = |M| + k + 1.
- Each of these paths is of length at least  $\ell$ .

### Lemma 98

*P* is of length at least  $\ell + 1$ . This shows that the length of a shortest augmenting path increases between two phases of the Hopcroft-Karp algorithm.

### Proof.

- ► If P does not intersect any of the P<sub>1</sub>,..., P<sub>k</sub>, this follows from the maximality of the set {P<sub>1</sub>,..., P<sub>k</sub>}.
- Otherwise, at least one edge from P coincides with an edge from paths {P<sub>1</sub>,...,P<sub>k</sub>}.
- This edge is not contained in *A*.
- Hence,  $|A| \le k\ell + |P| 1$ .
- ► The lower bound on |A| gives  $(k+1)\ell \le |A| \le k\ell + |P| 1$ , and hence  $|P| \ge \ell + 1$ .

If the shortest augmenting path w.r.t. a matching M has  $\ell$  edges then the cardinality of the maximum matching is of size at most  $|M| + \frac{|V|}{\ell+1}$ .

#### Proof.

The symmetric difference between M and  $M^*$  contains  $|M^*| - |M|$  vertex-disjoint augmenting paths. Each of these paths contains at least  $\ell + 1$  vertices. Hence, there can be at most  $\frac{|V|}{\ell+1}$  of them.

#### Lemma 99

The Hopcroft-Karp algorithm requires at most  $2\sqrt{|V|}$  phases.

### Proof.

- ▶ After iteration  $\lfloor \sqrt{|V|} \rfloor$  the length of a shortest augmenting path must be at least  $\lfloor \sqrt{|V|} \rfloor + 1 \ge \sqrt{|V|}$ .
- ► Hence, there can be at most  $|V|/(\sqrt{|V|} + 1) \le \sqrt{|V|}$  additional augmentations.

#### Lemma 100

One phase of the Hopcroft-Karp algorithm can be implemented in time  $\mathcal{O}(m)$ .

construct a "level graph" G':

- construct Level 0 that includes all free vertices on left side L
- construct Level 1 containing all neighbors of Level 0
- construct Level 2 containing matching neighbors of Level 1
- construct Level 3 containing all neighbors of Level 2
- ...

stop when a level (apart from Level 0) contains a free vertex can be done in time O(m) by a modified BFS

- a shortest augmenting path must go from Level 0 to the last layer constructed
- it can only use edges between layers
- construct a maximal set of vertex disjoint augmenting path connecting the layers
- for this, go forward until you either reach a free vertex or you reach a "dead end" v
- if you reach a free vertex delete the augmenting path and all incident edges from the graph
- if you reach a dead end backtrack and delete v together with its incident edges

See lecture versions of the slides.

## **Analysis: Shortest Augmenting Path for Flows**

#### cost for searches during a phase is $\mathcal{O}(mn)$

- a search (successful or unsuccessful) takes time  $\mathcal{O}(n)$
- a search deletes at least one edge from the level graph

#### there are at most *n* phases

Time:  $\mathcal{O}(mn^2)$ .

## Analysis for Unit-capacity Simple Networks

#### cost for searches during a phase is $\mathcal{O}(m)$

an edge/vertex is traversed at most twice

#### need at most $\mathcal{O}(\sqrt{n})$ phases

- after  $\sqrt{n}$  phases there is a cut of size at most  $\sqrt{n}$  in the residual graph
- hence at most  $\sqrt{n}$  additional augmentations required

Time:  $\mathcal{O}(m\sqrt{n})$ .
