#### 9 Union Find

**Union Find Data Structure P:** Maintains a partition of **disjoint** sets over elements.

- **P.** makeset(x): Given an element x, adds x to the data-structure and creates a singleton set that contains only this element. Returns a locator/handle for x in the data-structure.
- ▶  $\mathcal{P}$ . find(x): Given a handle for an element x; find the set that contains x. Returns a representative/identifier for this set.
- **P.** union(x, y): Given two elements x, and y that are currently in sets  $S_{\nu}$  and  $S_{\nu}$ , respectively, the function replaces  $S_{\chi}$  and  $S_{\gamma}$  by  $S_{\chi} \cup S_{\gamma}$  and returns an identifier for the new set.

## **List Implementation**

- The elements of a set are stored in a list; each node has a backward pointer to the head.
- The head of the list contains the identifier for the set and a field that stores the size of the set.

- ightharpoonup makeset(x) can be performed in constant time.
- $ightharpoonup \operatorname{find}(x)$  can be performed in constant time.

## **List Implementation**

#### union(x, y)

- ▶ Determine sets  $S_X$  and  $S_Y$ .
- ► Traverse the smaller list (say  $S_y$ ), and change all backward pointers to the head of list  $S_x$ .
- ▶ Insert list  $S_{\gamma}$  at the head of  $S_{\chi}$ .
- ▶ Adjust the size-field of list  $S_x$ .
- ► Time:  $\min\{|S_x|, |S_y|\}$ .

# List Implementation

## **List Implementation**

## **List Implementation**

## Running times:

- $ightharpoonup \operatorname{find}(x)$ : constant
- ightharpoonup makeset(x): constant
- union(x, y):  $\mathcal{O}(n)$ , where n denotes the number of elements contained in the set system.

9 Union Find

## **List Implementation**

#### Lemma 1

The list implementation for the ADT union find fulfills the following amortized time bounds:

 $ightharpoonup find(x): \mathcal{O}(1)$ .

ightharpoonup makeset(x):  $\mathcal{O}(\log n)$ .

▶ union(x, y):  $\mathcal{O}(1)$ .

Harald Räcke

9 Union Find

15. Nov. 2024

122/143

### **List Implementation**

- For an operation whose actual cost exceeds the amortized cost we charge the excess to the elements involved.
- ▶ In total we will charge at most  $O(\log n)$  to an element (regardless of the request sequence).
- ► For each element a makeset operation occurs as the first operation involving this element.
- We inflate the amortized cost of the makeset-operation to  $\Theta(\log n)$ , i.e., at this point we fill the bank account of the element to  $\Theta(\log n)$ .
- Later operations charge the account but the balance never drops below zero.

## The Accounting Method for Amortized Time Bounds

- ► There is a bank account for every element in the data structure.
- Initially the balance on all accounts is zero.
- Whenever for an operation the amortized time bound exceeds the actual cost, the difference is credited to some bank accounts of elements involved.
- Whenever for an operation the actual cost exceeds the amortized time bound, the difference is charged to bank accounts of some of the elements involved.
- ▶ If we can find a charging scheme that guarantees that balances always stay positive the amortized time bounds are proven.

Harald Räcke

9 Union Find

15. Nov. 2024

123/143

## List Implementation

**makeset**(x): The actual cost is  $\mathcal{O}(1)$ . Due to the cost inflation the amortized cost is  $\mathcal{O}(\log n)$ .

**find**(x): For this operation we define the amortized cost and the actual cost to be the same. Hence, this operation does not change any accounts. Cost:  $\mathcal{O}(1)$ .

#### union(x, y):

- ▶ If  $S_x = S_y$  the cost is constant; no bank accounts change.
- ▶ Otw. the actual cost is  $\mathcal{O}(\min\{|S_x|, |S_y|\})$ .
- Assume wlog. that  $S_X$  is the smaller set; let c denote the hidden constant, i.e., the actual cost is at most  $c \cdot |S_X|$ .
- ▶ Charge c to every element in set  $S_x$ .

## **List Implementation**

#### Lemma 2

An element is charged at most  $\lfloor \log_2 n \rfloor$  times, where n is the total number of elements in the set system.

#### Proof.

Whenever an element x is charged the number of elements in x's set doubles. This can happen at most  $\lfloor \log n \rfloor$  times.

Harald Räcke

9 Union Find

15. Nov. 2024

126/143

## Implementation via Trees

#### makeset(x)

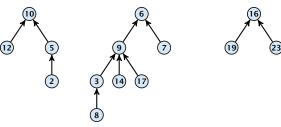

- Create a singleton tree. Return pointer to the root.
- ▶ Time:  $\mathcal{O}(1)$ .

#### find(x)

- Start at element x in the tree. Go upwards until you reach the root.
- ▶ Time:  $\mathcal{O}(\text{level}(x))$ , where level(x) is the distance of element x to the root in its tree. Not constant.

## **Implementation via Trees**

- Maintain nodes of a set in a tree.
- ▶ The root of the tree is the label of the set.
- Only pointer to parent exists; we cannot list all elements of a given set.
- Example:

Set system {2, 5, 10, 12}, {3, 6, 7, 8, 9, 14, 17}, {16, 19, 23}.

Harald Räcke

9 Union Find

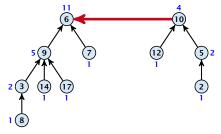

15. Nov. 2024 127/143

### **Implementation via Trees**

To support union we store the size of a tree in its root.

#### union(x, y)

- ▶ Perform  $a \leftarrow \text{find}(x)$ ;  $b \leftarrow \text{find}(y)$ . Then: link(a, b).
- $\blacktriangleright$  link(a, b) attaches the smaller tree as the child of the larger.
- In addition it updates the size-field of the new root.

▶ Time: constant for link(a, b) plus two find-operations.

## **Implementation via Trees**

#### Lemma 3

The running time (non-amortized!!!) for find(x) is  $O(\log n)$ .

#### Proof.

- ▶ When we attach a tree with root c to become a child of a tree with root p, then  $\operatorname{size}(p) \ge 2\operatorname{size}(c)$ , where size denotes the value of the size-field right after the operation.
- ► After that the value of size(c) stays fixed, while the value of size(p) may still increase.
- ► Hence, at any point in time a tree fulfills  $size(p) \ge 2 \, size(c)$ , for any pair of nodes (p,c), where p is a parent of c.

Harald Räcke

9 Union Find

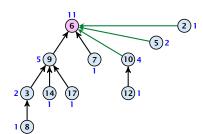

15. Nov. 2024

130/143

### **Path Compression**

#### find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

One could change the algorithm to update the size-fields. This could be done without asymptotically affecting the running time.

However, the only size-field that is actually required is the field at the root, which is always correct.

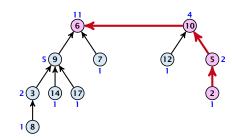

We will only use the other size-fields for the proof of Theorem 6.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

## **Path Compression**

#### find(x):

- ► Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

Harald Räcke

9 Union Find

15. Nov. 2024

131/143

## **Path Compression**

Asymptotically the cost for a find-operation does not increase due to the path compression heuristic.

However, for a worst-case analysis there is no improvement on the running time. It can still happen that a find-operation takes time  $\mathcal{O}(\log n)$ .

## **Amortized Analysis**

#### **Definitions:**

▶ size(v) = the number of nodes that were in the sub-tree rooted at <math>v when v became the child of another node (or the number of nodes if v is the root).

Note that this is the same as the size of  $\nu$ 's subtree in the case that there are no find-operations.

- $ightharpoonup rank(v) = \lfloor \log(\operatorname{size}(v)) \rfloor.$
- ightharpoonup  $\Rightarrow$  size $(v) \ge 2^{\operatorname{rank}(v)}$ .

#### Lemma 4

The rank of a parent must be strictly larger than the rank of a child.

9 Union Find

15. Nov. 2024

133/143

### **Amortized Analysis**

We define

and

$$\log^*(n) := \min\{i \mid \text{tow}(i) \ge n\} .$$

#### Theorem 6

Union find with path compression fulfills the following amortized running times:

- ightharpoonup makeset(x) :  $\mathcal{O}(\log^*(n))$
- $ightharpoonup find(x) : \mathcal{O}(\log^*(n))$
- ▶ union(x, y) :  $\mathcal{O}(\log^*(n))$

# Harald Räcke

## **Amortized Analysis**

#### Lemma 5

There are at most  $n/2^s$  nodes of rank s.

#### Proof.

- Let's say a node v sees node x if v is in x's sub-tree at the time that x becomes a child.
- A node v sees at most one node of rank s during the running time of the algorithm.
- ► This holds because the rank-sequence of the roots of the different trees that contain v during the running time of the algorithm is a strictly increasing sequence.
- ► Hence, every node *sees* at most one rank s node, but every rank s node is seen by at least  $2^s$  different nodes.

9 Union Find

15. Nov. 2024

134/143

## **Amortized Analysis**

In the following we assume  $n \ge 2$ .

#### rank-group:

- ▶ A node with rank rank(v) is in rank group  $log^*(rank(v))$ .
- ► The rank-group g = 0 contains only nodes with rank 0 or rank 1.
- A rank group  $g \ge 1$  contains ranks tow(g-1) + 1, ..., tow(g).
- ► The maximum non-empty rank group is  $\log^*(\lfloor \log n \rfloor) \le \log^*(n) 1$  (which holds for  $n \ge 2$ ).
- $\blacktriangleright$  Hence, the total number of rank-groups is at most  $\log^* n$ .

## **Amortized Analysis**

#### **Accounting Scheme:**

- create an account for every find-operation
- ightharpoonup create an account for every node v

The cost for a find-operation is equal to the length of the path traversed. We charge the cost for going from v to parent[v] as follows:

- ► If parent[v] is the root we charge the cost to the find-account.
- ▶ If the group-number of rank(v) is the same as that of rank(parent[v]) (before starting path compression) we charge the cost to the node-account of v.
- ▶ Otherwise we charge the cost to the find-account.

9 Union Find

15. Nov. 2024

137/143

## **Amortized Analysis**

#### What is the total charge made to nodes?

► The total charge is at most

$$\sum_{g} n(g) \cdot \text{tow}(g) ,$$

where n(g) is the number of nodes in group g.

## **Amortized Analysis**

#### **Observations:**

- ▶ A find-account is charged at most  $\log^*(n)$  times (once for the root and at most  $\log^*(n) 1$  times when increasing the rank-group).
- After a node v is charged its parent-edge is re-assigned. The rank of the parent strictly increases.
- After some charges to v the parent will be in a larger rank-group.  $\Rightarrow v$  will never be charged again.
- ► The total charge made to a node in rank-group g is at most  $tow(g) tow(g-1) 1 \le tow(g)$ .

9 Union Find

15. Nov. 2024

138/143

## **Amortized Analysis**

For  $g \ge 1$  we have

$$n(g) \le \sum_{s=\text{tow}(g-1)+1}^{\text{tow}(g)} \frac{n}{2^s} \le \sum_{s=\text{tow}(g-1)+1}^{\infty} \frac{n}{2^s}$$

$$= \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\infty} \frac{1}{2^s} = \frac{n}{2^{\text{tow}(g-1)+1}} \cdot 2$$

$$= \frac{n}{2^{\text{tow}(g-1)}} = \frac{n}{\text{tow}(g)}.$$

Hence,

$$\sum_{g} n(g) \operatorname{tow}(g) \le n(0) \operatorname{tow}(0) + \sum_{g \ge 1} n(g) \operatorname{tow}(g) \le n \log^*(n)$$

## **Amortized Analysis**

Without loss of generality we can assume that all makeset-operations occur at the start.

This means if we inflate the cost of makeset to  $\log^* n$  and add this to the node account of v then the balances of all node accounts will sum up to a positive value (this is sufficient to obtain an amortized bound).

9 Union Find

15 Nov 2024

141/143

#### **Amortized Analysis**

$$A(x,y) = \begin{cases} y+1 & \text{if } x = 0\\ A(x-1,1) & \text{if } y = 0\\ A(x-1,A(x,y-1)) & \text{otw.} \end{cases}$$

$$\alpha(m, n) = \min\{i \ge 1 : A(i, \lfloor m/n \rfloor) \ge \log n\}$$

- A(0, y) = y + 1
- A(1, y) = y + 2
- A(2, y) = 2y + 3
- $A(3, y) = 2^{y+3} 3$
- $A(4, y) = 2^{2^{2^2}} -3$ y+3 times

## **Amortized Analysis**

The analysis is not tight. In fact it has been shown that the amortized time for the union-find data structure with path compression is  $\mathcal{O}(\alpha(m,n))$ , where  $\alpha(m,n)$  is the inverse Ackermann function which grows a lot lot slower than  $\log^* n$ . (Here, we consider the average running time of m operations on at most n elements).

There is also a lower bound of  $\Omega(\alpha(m, n))$ .

Harald Räcke

9 Union Find

15 Nov 2024

142/143

$$\alpha(m,n) = \min\{i \ge 1 : A(i,\lfloor m/n \rfloor) \ge \log n\}$$

Union find data structures are discussed in Chapter 21 of [CLRS90b] and [CLRS90c] and in Chapter 22 of [CLRS90a]. The analysis of union by rank with path compression can be found in [CLRS90a] but neither in [CLRS90b] in nor in [CLRS90c]. The latter books contains a more involved analysis that gives a better bound than  $O(\log^* n)$ .

A description of the  $\mathcal{O}(\log^*)$ -bound can also be found in Chapter 4.8 of [AHU74].
